In the department of *S. Scripture* the Dominicans were medieval pioneers in the critical study of the Bible, whether in the original text or in translations. The Barnabite Fr. Vereclone (nineteenth century) says they were the first to resume the critical work of Origen (*q.v.*) and St. Jerome (*q.v.*). The *Correctoria* of the Latin versions were brought out almost exclusively by the Dominicans up to the year 1267, and they labored incessantly at this work until the authentic Clementine Vulgate was published in 1592. Hugh of St. Cher, in the thirteenth century, wrote the first biblical concordance. Santes Pagnini (d. 1541) was the first after St. Jerome to make a complete translation of the Bible from the original sources. Sixtus of Sienna (d. 1569), in his *Bibliotheca Sacra*, inaugurated the systematic study of the Bible, but "the real creator of the science of Introduction," writes Father Cornely, S.J., "was Father Thomas Milante" (d. 1742). It is worthy of note that as early as the thirteenth century the Dominicans sought to popularize the Bible. Their position at Paris makes it almost certain that they took a prominent part in producing the French version of that century (1226-1250). An elegant Italian version is attributed to James of Voragine (d. 1298), author of the *Golden Legend*. An Armenian translation, made under the direction of Bartholomew Parvus (d. c. 1360) appeared about the middle of the fourteenth century. Chronicles of the Dominican Sisters of Nuremberg in the fifteenth century prove that they and other nuns were employed in copying biblical manuscripts, and that they read the Bible in the vernacular. John Rellach and others translated portions of the Bible into German about the middle of the fifteenth century (more than sixty years before Luther's translation appeared).

The study of the Oriental languages was urged by the first general chapters of the order, that study being regarded as a necessary preparation for missionary work and for the scientific study of the Bible. Augustine Giustiniani (1536) opened the first official course of Hebrew in the University of Paris. He prepared also the first modern polyglot Bible in seven versions, and five languages, Hebrew, Chaldaic, Arabic, Greek, and Latin (three

versions); an eighth column contained *annotationes et scholia*. Owing to lack of funds, only the Psalter was published. Raymond Martin (1286), author of the *Pugio Fidei*, was a distinguished Orientalist, speaking and writing with ease Hebrew, Chaldaic, and Arabic. In our own times the best traditions of the order are worthily upheld in the Biblical School of St. Stephen, Jerusalem. Through the *Revue Biblique* and various monographs, treating all subjects pertaining to biblical studies, Father Lagrange and his confreres hold high places in the list of Orientalists and biblical scholars. Father Scheil, the first to publish the *Code of Hammurabi*, is the greatest Assyriologist of France, being sent frequently on scientific missions by the French government.

St. Raymond of Pennaforte (d. 1275) was a promoter of various educational works. At his request St. Thomas composed the *Summa contra Gentes*, directed principally against the Moors of Spain. By composing, at the command of Gregory IX, the book of the *Decretals*, Raymond became the "Father of Canon Law" (*q.v.*). In this branch of ecclesiastical learning he had many followers, among whom some of the most celebrated are Thomas Bromyard (d. 1390), Thomas Turresemata (d. 1648), and Peter Passerini (d. 1677). Church history, strongly recommended in the regulations for studies, received attention from the beginning. In this field the order is represented by many writers (see Introduction to any good history of the Church), the most noted being St. Antoninus (d. 1459), Graveson (d. 1733), and Natalis Alexander (d. 1724), whose monumental work is held in the highest esteem.

At Dublin, in 1248, the Dominicans opened (on Usher's Island) a school in which all branches of knowledge were taught gratuitously (see Drane, *Christian Schools and Scholars*, p. 443; *Dublin Review*, September, 1845). In 1563, Vincent Justiniani, Master of the order, saved the University of Freiburg (Breisgau) from extinction, by establishing a *Studium Generale* at Eulingen (Janssen, Vol. VII, p. 172). The University of Lima was established by the Dominicans in 1551, thus antedating Harvard by eighty-five years. They also founded the University of St. Thomas at Manila (P. I.) in 1645. President Taft, when he was Governor-General of the Philippine Islands, reopened the classes in this university. During the past two years two American Dominicans have been added to the teaching staff. At Rome the Minerva College (foundation dates from 1255) has ranked as a pontifical university since 1580. In 1890 Dominicans were placed in charge of the theological department of the University of Fribourg, Switzerland (founded in 1889). The professors of this institution are the editors of the *Revue Thomiste*, an esteemed theological periodical begun in 1892. Popular education was not a special aim of the Dominicans, except in so far as it may have been a

necessary part of their apostolic mission; nevertheless, their labors contributed much to educate the people. St. Thomas' *Summa* furnished the material for Dante's *Divina Commedia*. Vincent of Beauvais' *Great Mirror*, a thirteenth-century encyclopedia, was, according to Rohrbacher (*Ecclesiastical History*, Vol. XVIII) "an epitome of all that man, up to that time, knew in nature, science, art, philosophy, and history." James of Voragine's *Golden Legend* (translated by Longfellow) was a manual of popular instruction. The writings of Tauler and B. Henry Suso exercised a powerful influence on German prose. Jordan of Pisa, Passavanti, Cavalea, and B. John Dominic contributed much to the perfection of the Italian tongue. St. Antoninus, Fra Angelico, and a host of others (see Cartier) elevated Christian art. Savonarola, by his preaching and writings, by his life and tragic death, taught lessons that have extended far beyond the Florentine Republic. College work has not been a special branch of Dominican activity. The old universities offered courses that would be considered college courses to-day. In many places the doors of the *Studia*, in which candidates of the order were trained, were opened to all promising young men; and in countries where colleges were wanting the Dominicans established colleges and schools, wrote grammars, geographies, and other manuals. Father Lacordaire, in 1852, founded the Third Order of Teaching Dominicans, who had several very promising colleges harboring the flower of young manhood in France, before recent decrees of the government came to hamper, if not to destroy, their educational work.

The Dominicans of the United States, being devoted almost exclusively to missionary work, have been compelled to confine their educational endeavors to the training of their own students. For many years studies have been organized in accordance with the strict requirements of the time-honored rules, and the new college (a *Studium Generale*) opened in 1905 near the Catholic University at Washington has revived the best traditions of the order. In the first half of the last century, in view of special needs, the Fathers of St. Joseph's Province (founded 1805) established colleges in Kentucky, Ohio, and Wisconsin, but withdrew in time from this field of labor in order to devote themselves to their own special work.

In Europe, during the last half of the nineteenth century, the venerable Father Guglielmotti published a *Marine Dictionary*, the best work of its kind, highly esteemed in Italy and elsewhere. Father Henry Denifle, a scholar and educator of world-wide renown, published the *Chartularium Universitatis Parisiensis*, and other epoch-making works. He was journeying to England, to be crowned as an honorary doctor of the Cambridge University, when death claimed him at Munich (June 10, 1905). Father Weiss, professor in the University of

Fribourg (Switzerland), is hailed as a distinguished apologist and an authority on social questions, whilst the superior style of his writings marks him as a master of German prose. His confrere, Father Mandonnet, is a noted historian and writer. His monograph on *Siger de Brabant* is a standard for the history of Averroism. Father Monsabré's *Exposition du Dogme Catholique* (Conferences at Notre Dame, Paris) probably has never been surpassed as a popular, scientific, and yet theological explanation of Catholic doctrine. Exiled French Dominicans, now located at Kain, Belgium, publish the *Revue des Sciences Philosophiques et Théologiques*, which has received much praise.

The Dominican Sisters, whether of the Second Order (inclosed) or of the Third Order, deserve more than a passing notice. The work of the Second Order was limited to receiving a small number of girls to be educated by the Sisters. In 1609 the Convent of Avignon received as a member of the community the Ven. Juliana Anna Morrell, who had publicly defended theses in philosophy and theology, and who was generally known as "The Doctress." The Conventual Tertiaries have devoted themselves to educational work in all countries where they have been established, especially in England, Ireland, and America. Mother Raphael (d. 1893), better known as A. T. Drane, was a highly gifted writer. Her *Christian Schools and Scholars*, a monumental work, is a history of education from the beginning of the Christian era to the Council of Trent. In the United States to-day there are more than three thousand Dominican Sisters, divided into congregations or provinces, and who are devoted to educational work in orphanages, schools, and academies. Their field of labor extends from Canada to the Gulf of Mexico, from the Atlantic Ocean to the Pacific slope. Three Congregations, viz., Holy Rosary (Mother house, Sinsinawa, Wis.), St. Mary's of the Springs (Mother House, Columbus, Ohio), and Holy Name (Mother House, San Rafael, Cal.), offer courses which are officially recognized by the state universities of Wisconsin, Ohio, and California.

The rules of study and of graduation now in force in the Dominican Order are as follows: (1) After classics, seven or eight years of study of philosophy and theology (four of the eight years devoted to the *Summa* of St. Thomas), there being frequent examinations and exercises in speaking and writing—lead to the lectorate (*Sacrae Theologiae Lector*, S. T. L.). In 1907 the General Chapter of Viterbo prescribed two years of supplementary study, i.e. after obtaining the lectorate, in a university before a Lector can be assigned to teaching. (2) After seven years of successful teaching, the candidate who has written a scientific work or a valuable dissertation may be admitted to pass the *Examen ad Gradus*, and becomes a Lector Praesentatus, i.e. a lector presented for the

mastership. (3) Six years more of successful teaching lead to the title of Master (S. T. M., i. e. *Sacrae Theologiae Magister*). The degree is conferred by the Master-General of the order, on petition of the province to which the teacher belongs. D. J. K.

**DONATUS, ÆLIUS** (fourth century A.D.).—A Roman grammarian and rhetorician, an author and a teacher of renown, numbering St. Jerome among his pupils. He produced a number of commentaries of note, especially those on Vergil and Terence. His *Ars Grammatica*, written about the middle of the fourth century A.D., formed the basis of nearly all of the treatises on that subject written during the Middle Ages, and was itself the most generally used text on that subject. The second of the three parts, *On the Eight Parts of Speech*, was even more widely used; so generally, in fact, that the term *donat* was used in the literature of that time, as in Chaucer and Langland, as synonymous with an introduction, as a *Donat into Christian Religion*. This abbreviated form was practically a primer, as in ordinary type it is only eight or nine pages in length. It was still commonly used, ordinarily with a vernacular interlinear, in the

seventeenth century. This grammar, either in its full or abbreviated form, is one of the commonest of early printed books, and exists yet in more than a thousand manuscripts of earlier date.

**DORMITORIES**.—The historical connection of dormitories and boarding clubs with the development of units of organization and administration in colleges and universities has been shown in the article upon Boarding Schools (*q.v.*). (See also CAMBRIDGE; OXFORD; PUBLIC SCHOOLS; UNIVERSITIES.) In France and England, where the *internat* type of schools predominates in the education of the upper classes, the various forms of sleeping rooms which are found go back to two general classes. (1) An open hall in which the persons either (*a*) sleep in beds arranged in rows, or (*b*) are separated by low wooden partitions with hangings at the entrances. (2) Separate cells opening on a corridor. The primitive form was used by the Benedictines, and was brought back among the Cistercians by Bernard, but the more luxurious members at Cluny allowed the greater differentiation in the tenth century and it became the type after the fourteenth century. Modern usage, especially in America, often applies the term to the earlier college, where students lived in chambers, or to the quasi-public boarding house. The various methods of arrangement discussed in modern schools go back to these ancient forms for instance, the cubicle, which is accounted in some schools a satisfactory mean between the extremes, is derived from 1 (*b*). The problems of places for eating, recreation, work, etc., are involved, and one finds interesting variations in meeting these, as the little "dens" for study at Rugby and the large study halls of some other schools, each considered superior to others by those using it. Difficulties of economical heating have seemed to justify some conditions of the past, but the subject has had remarkably little expert attention, and present arrangements lag far behind modern progress in heating and ventilation.

**England**.—The dormitory has played a more important part in student life in England than elsewhere, since so much of the training of the boy is furnished through the life as there organized. That dormitories were used from the earliest time by the large English schools is quite clear, for there are among the manuscripts at Westminster Abbey some elaborate rules for the behavior of the boys in the choir school, and these rules give some general idea of

TYPES OF DORMITORIES.

## DORMITORIES

the sleeping arrangements provided for the boys. The rules say (*inter alia*), "when they get up in the morning therefore they should mark themselves piously with the sign of the cross. . . . They must cover their beds with their mats and coverlets properly and leave their chamber quietly and without noise altogether, and must wash their hands and go to the church modestly, not running or jumping or clattering. . . . Whoever at the hour of going to bed upsets the bed of his companions or hides his clothes or throws his shoes or his pillows from one end of the room to the other, or loses his temper, or disturbs the dormitory, is to be severely punished on the next day; when they go to bed they are to behave in the same way as when they get up, marking themselves and their beds with the sign of the cross." Here is presented a clear picture of a dormitory in the thirteenth century, and it is certain that for centuries after this time the same method of providing sleeping accommodation prevailed. Indeed, much the same system is found to prevail at Westminster in the nineteenth century. In 1839 Frank Buckland (the naturalist) writes concerning Winchester: "The beds in 'chambers' are, I believe, as old as William of Wykeham himself; they are made of very thick oak planks, and there is a hollow for the bed clothes, after the style of the beds for foxhounds in kennels." Buckland went through the processes of "launch" and "toe fit tie." In the first case, the mattress and sleeping boy are dragged into the middle of the room; in the second, whipcord is tied round the big toe of the boy, "the whip cord was so ingeniously twisted among the beds that it was impossible to find out who pulled it." The latest arrival in college is called "Junior in chambers" who had, in Buckland's time, to get up when the early chapel bell rang, call all the boys, light the fires, put out the prefects' washing tubs, clean (on Sunday) the wash and basins at "conduit" (two water taps in the open), make coffee for the prefects, clean the knives, make plum puddings, etc. (See FAGGING.) The only change that has come over or into the average school dormitory is the introduction of the cubicle. It will be convenient to describe two modern dormitories, one in a somewhat small school (Giggleswick) and one in a great school (Eton).

The mass of the boys at Eton live in "houses" under housemasters, and in the houses each boy has a separate bedroom used as a study by day, the beds being turned up to the wall. Seventy boys are on the ancient foundation as scholars, and these live in "college" (a separate block of buildings consisting of the original school buildings and some nineteenth century additions). At the present time only the lowest fifteen of the boys in college live in "Long Chamber." This was originally a long room large enough to accommodate the whole of the seventy scholars. It has now been

## DORMITORIES

reduced to a fraction of its original size, a large part of it having been divided into separate rooms for the older boys. The remaining part is still called "Chamber." It is divided into fifteen cubicles by wooden partitions. The partitions go only about one third of the way up the walls, being about eight feet high. A curtain is arranged at the front of each cubicle, or "stall," as it is called. Each stall is fitted with a bed, which folds up into a kind of tall wooden box, a writing bureau surmounted by a book cupboard, and comprising drawers for clothes, a Windsor chair, bath, and tin pan for dirty clothes. In the center of the wall or "chamber" is a fireplace, opposite to which is an old round oak table; the external walls of the cubicles on either side of the fireplace have benches fixed to them. On the table there is always kept a jug of drinking water from the old pump in the cloisters on the other side of the open "school yard." "Chamber" is managed by the top boy in it, who is called "Captain of Chamber." It is his duty to keep order day and night, though at the time when "chamber" is going to bed, a member of sixth form always patrols to see that all is orderly. The boys take it in order to keep up the fire in winter and to keep the waterjug filled. The captain has power to enforce his orders by mild corporal punishment, administered either with a hair brush, or a "syphon," that is a rubber tube used to convey water from the taps to the baths. All the boys in "Chamber" are "fags." And every boy in "Chamber" has to run to the summons when a member of sixth form or headmaster's division calls "Here!" within earshot. "Chamber" has a life of its own; its own debating society, its own games of cricket and football, made up to the requisite size by the inclusion of the necessary number of boys from those next above "Chamber," a separate room (called "Chamber Tearoom") for its meals, its own athletic sports and (single wicket) cricket, and rowing sweepstakes. Moreover, it has annual matches against the inhabitants of the other tearooms (known as Chamber *v.* Tearoom), which arouse considerable interest in college.

At Giggleswick the four chief dormitories are about seventy feet long, by thirty feet wide, and fifteen feet high. There are in each some twenty-four cubicles twelve feet by six feet (ranged on each side) partitioned by pitch pine boards eight feet high. Each cubicle is set from the outer wall, and contains a bed, a dressing chest, a washstand, and a chair. There is one small dormitory. The long dormitories are controlled by two "seniors," the smaller one by one "senior." With the exception of some double rooms for brothers, the whole school is boarded on the dormitory system. The continuous use, for many centuries, of the dormitory system is one of the "notes" of English education. It is to be remembered that it

never extended at any time to Oxford or Cambridge.

**Germany.** — In German discussions of the subject, the term *Pensionat* is reserved for conditions in which the family type predominates, and it does not include living arrangements in which the family life is lost. Dietsch, in an article on *Alumnate* in Schmid's *Encyclopædia*, notes the following groups: (1) *Zellenwirtschaft* (two students in a room in which they work and sleep); (2) *Stubenwirtschaft* (four in a workroom with adjoining sleeping rooms); (3) *Saalwirtschaft* (ten or twelve in a workroom, with two or three times as many in a dormitory). In some of the states of Germany, any scheme which departs from the barracks form of dormitory for boys in boarding schools is effectively discouraged by the governmental authorities. The reason given is that the students will become unfitted for the accommodations furnished during the term of military service.

**United States.** — The state institutions in this country have attempted to keep free from responsibility for the living accommodations for their students. This has been due in large part to inadequate provision of funds. Usually when dormitories have been provided they have descended from some earlier form of the school under private control, or have been established as a result of some special influence. There has been a growing tendency to exercise greater authority over students in these matters, as *e.g.* a ruling sometimes found that girls must not room in houses in which no provision is made for receiving callers. Spasmodic efforts at inspection have revealed most appalling conditions taken as a matter of course, and there is a growing sense of responsibility for meeting needs more adequately. The University of Wisconsin has a definite policy, which is coming into operation as fast as funds are made available. The University of Michigan, through its Women's Union, is making a beginning in the control of several houses for residence purposes. The movement, in general, is toward more homelike conditions. Often there has been a failure to take account of the effect of several years' life during the growing period, in which the place basis is lacking in the development of the instincts of ownership, as well as other important tendencies. There is a marked difference in the evidence of certain interests and activities in the life of a boarding school boy who has some place to call his own and another who has nothing but a locker or a drawer in which to center his material possessions.

Serious criticism of existing conditions in our colleges has often been made, but for the most part, the only serious attempt toward meeting this need in recent times has fallen to the Greek letter fraternities (*q.v.*). Where the fraternities have been strongest, during the quarter of a century in which they have provided houses or lodges, the colleges have ceased to build new

dormitories. Thus at Amherst, in 1870, fifty-three per cent of 225 students were in dormitories; in 1905, 24 per cent of 455 were in dormitories and 43 per cent in fraternity houses. Thus the answering of the problem of finding at least a partial substitute for college home life has been left largely to the students. The financial aspects of the student housing problem are very important, whether attempted by the students or by the college. The modern dormitory represents a permanent investment of from \$500 to \$2000 for every student housed.

Other aspects of this problem are discussed under other subjects. See BOARDING SCHOOL; COLLEGE; FRATERNITIES; PRIVATE SCHOOLS; UNIVERSITIES.

**DORPAT, UNIVERSITY OF.** — Founded in 1632 by Gustavus Adolphus, but closed under the rule of Peter the Great of Russia. It was restored in 1802, and in 1803-1804 became one of the imperial universities. The statutes and regulations have been revised several times, the last revision being in 1884. In 1892 the official title became the Imperial University of Jurjev. Faculties of theology, law, medicine, arts, and sciences are maintained. The instruction is carried on in Russian and German. The town has a large German population, and the university is a stronghold of German scholarship in Russia. At one time a department for the training of professors was maintained. (See H. Barnard, *Superior Instruction*, p. 839. Hartford, 1873.) In 1909 there were enrolled 2815 students, of whom 1233 were in the medical faculty.

**DÖRPFELD, FRIEDRICH WILHELM** (1824-1893). — A distinguished German schoolman and educational writer of the Herbartian school. Born in Sellscheid in the Rhine province, he attended the teachers' seminary in Mörs, and became, in 1850, teacher and later on principal of a school in

Barmen, where he taught for thirty years. In 1880 he was retired, and the rest of his life was devoted to literary activity. Dörpfeld's chief service to pedagogy consists in his application of Herbart's ideas to the theory and practice of the elementary school. For this he was well fitted on account of his philosophical insight and his school experience. His work on *Denken und Gedächtnis* (1886), (*The Connection between Thought and Memory*, edited in English by Herman T. Lukens, Boston, 1895), is still one of the most valuable monographs in pedagogical psychology. Dörpfeld, however, took a great step in advance of Herbart in emphasizing the social side of education. He advocated an elementary study of sociology in the school, not as a separate subject of instruction, but rather as a point of view in the treatment of history, geography, and other studies. With regard to school organization, he strongly favored the institution of self-governing school communities, the internal affairs of which should be free from the interference of both Church and State. His complete works were published in 1894. F. M.

**DORT, SYNOD OF.**—The most notable synod of the Reformed Dutch Church, assembled 1618-1619, in Dort (Dordrecht) at the call of the States General of the United Netherlands for the purpose of committing the church to Calvinism. Delegates came from the provincial synods, the several states, and from Switzerland, Germany, and England. Education received attention. Catechizing was regulated. Schools were demanded, "not only in cities, but also in towns and country places where heretofore none have existed." Request was made of the magistrates for properly qualified teachers, and "that the children of the poor may be gratuitously instructed." Church attendance of pupils was required. All teachers, of whatever grade, must sign the confession of faith as newly interpreted. Local and general ecclesiastical visitation of schools was provided. The States General were petitioned to reform trivial schools and universities. Doctrinally, the influence of the synod was great; and in the more stringent enforcement of the creed the schools were affected. On the whole, educational development was not much furthered. The special school enactments were little, if at all, in advance of previous similar enactments or of general public opinion, and besides had to depend for their enforcement upon the ordinary school laws of the several cities and states.

**DOUBLE IMAGES.**—The two eyes always receive impressions from any object in the field of vision. These two images are ordinarily fused. (See FUSION; BINOCULAR VISION.) In some cases, however, the fusion is impossible; then the individual derives a separate experience from each of the images and is disturbed by double vision of the object. One of the simplest methods of producing double images is to push one eyeball out of its normal position. The image from a given object then falls upon a portion of the retina which is not usually related to the portions stimulated by the same object in the other eye. The two images are then said to fall on noncorresponding points of the retina. (See CORRESPONDING POINTS.) In some cases the movements of the two eyes are of such a character as to cause the images to fall on noncorresponding points. Such conditions arise in various forms of intoxication, when the nerve centers which control movement are incapacitated, and in certain pathological cases, such as diplopia. Certain abnormalities in the development of the eye muscles make it difficult for the individual to move his two eyes in perfect coördination. Such conditions sometimes depend on the different strength of different muscles, sometimes on their mode of attachment to the eyeballs. In either of these cases, normal visual perception is interfered with or is rendered impossible, or is achieved only at the expense of great physical effort. The correction of these difficulties is sometimes effected through surgical operations, sometimes through systematic training of the eye muscles, sometimes through the use of prismatic lenses. The failure to develop the proper coördination of the eye muscles is one of the very fertile causes of eye fatigue, and since no direct sensations from the fatigued muscles are provided, it is a very subtle form of abnormality. C. H. J.

**DOUBLE TRANSLATION.**—That practice in the teaching of a foreign language where the foreign text is translated into the vernacular and the vernacular rendition retranslated into the foreign tongue, the final translation being then compared with the original text. The method of double translation has been used mainly in the teaching of the classical languages, particularly Latin. In a modified form it is being widely introduced at present, particularly in the more recent English textbooks in foreign languages. It was probably a current method of the humanists in the period of their ascendancy. It was used in Johann Sturm's Gymnasium at Strassburg, and recommended as a method by Roger Ascham in his *Scholemaster*.

## DOUBT

See ASCHAM, ROGER; GREEK, STUDY OF; LATIN, STUDY OF; TRANSLATING.

**DOUBT.**—A state of incomplete or suspended judgment, to be distinguished from belief, either in its positive or negative form. Doubt is closely connected with the formation of belief. In the case of some particular belief, doubt may antedate certainty. Yet in many cases, doubt comes only after belief has taken form; and the belief, becoming then temporarily dissolved and tested, recrystallizes into its old form or into a new. For doubt to come *between* belief and belief, rather than to come either first or last, seems to be the normal course. In the history of the race and of the individual, doubt comes into prominence only at a late stage. The child, or the savage, forms his judgments less hesitatingly than does the more sophisticated man. This hesitation, which is useful so long as it tends to make belief more intelligent and more in harmony with wide experience, often far outlives its period of usefulness. Doubt now usurps the place of belief, and instead of aiding judgment makes judgment impossible. In certain diseased conditions, belief is thus perpetually hindered, and practical conduct becomes impossible because of unconquerable indecision.

**DOVER COLLEGE.**—See COLLEGE; COLLEGES, ENGLISH; GRAMMAR SCHOOLS; PUBLIC SCHOOLS.

**DOWNES, ANDREW.**—Regius professor of Greek in the University of Cambridge, 1585–1624. During the forty years of tenure of this post, Downes, “a scholar composed of Greek and industry” (as Fuller says), raised greatly the prestige of Greek studies from the low point they had reached in the latter part of the sixteenth century. From 1562 to 1567 as a boy, Downes was at the famous school of Shrewsbury, under Thomas Ashton, the first master. In 1593 Downes published the *Erasthenes* of Lysias, in the dedication of which he declares that next to God and his parents, he owed most to his old schoolmaster. Downes was one of the collaborators in Savile’s noble Eton edition of the work of St. Chrysostom (see Bois, JOHN), the greatest English edition of a classic author produced up to 1613. Downes was described by his contemporary Simonds D’Ewes (*Diary*) as “accounted the ablest Grecian of Christendom being no native of Greece,” though this was absurd, with Scaliger (*q.v.*) and Casaubon (*q.v.*) living.

## DRAKE UNIVERSITY

Downes was appointed one of the translators of the *Apocrypha* for the authorized version of the Bible, and was one of the six final revisers (see Bois, JOHN), but it was said of him that he would never leave Cambridge for the writings at Stationers’ Hall “till he was either fetched or threatened with a Pursuivant.” He was a correspondent (in Greek) with the great scholar, Isaac Casaubon (*q.v.*). F. W.

**DRAINAGE OF SCHOOLHOUSE AND GROUNDS.**—See ARCHITECTURE, SCHOOL.

### DRAKE UNIVERSITY, DES MOINES.

**IA.**—A coeducational institution opened Sept. 20, 1881. The departments include the college of liberal arts (1881), admission to which is by examination or certificate from an approved high school, and the college of the Bible (1884); the college of law, organized in 1875, was for six years a department of Simpson College, Indianola, Ia.; it was affiliated with Drake University in 1881 and purchased by the university in 1902; the original college of medicine, organized in 1881, and for the succeeding five years known as the Iowa Medical College (eclectic), was discontinued in 1887, when the Iowa College of Physicians, a private institution, became the medical department by affiliation. In October, 1908, the Keokuk Medical College, an institution which, under various names, had existed since 1844, was merged with the university school. The college of dentistry, established in 1897 as a department of the Keokuk Medical College, became a department of the university in 1908, when it succeeded the Des Moines College of Dental Surgery, affiliated with Drake University in 1900, but discontinued in 1906 for lack of support. The present school is well equipped. A college of pharmacy was organized in 1882, became an affiliated department in 1882, and a regular department in 1902, but was later discontinued for lack of support. In 1888 a normal department was established, now called the College of Education; it maintains a summer school, organized in 1890. The college of fine arts consists practically of the conservatory of music. Drake University suffered during its earlier career under the imputation of commercialism in its management and acquisition of schools. Its recent progress has, however, been rapid in the direction of higher standards.

Under an amended charter of June 12, 1907, the Board of Trustees became a self-perpetuating body of twenty-five members, including the president *ex officio*, without denominational restrictions of any kind. There are (1909) twenty-one life trustees who obtained office by giving \$1000 to the university; this form of membership has been abandoned. Six trustees of the twenty-five are nominated by the alumni. On Feb. 6, 1908, the university was accepted by the Carnegie Foundation for the Advance-

ment of Teaching (*q.v.*). The total productive endowment (1909) is \$432,351.17, producing an income of \$24,787.94. The total income is \$112,256.73; there is a debt, unprovided for, of \$28,500 (1909). Grounds, buildings, and equipment are valued at \$384,640.68. There were enrolled in 1910-1911, 1843 students. C. G.

**DRAMA AND EDUCATION.** — If "drama" be taken in its widest sense as action (*δράω*) it will include all forms of imitation which find expression by means of action. Thus a large proportion of the educational development of animals and human beings which springs from the "play" impulse is cognate to the drama. The little child who satisfies the "make-believe" desire is perpetually in the domain of the drama. The action games of the kindergarten are profoundly dramatic. All the imitative worlds of gesture and assumed speech, and accordingly all recitation and declamation, verges on the dramatic and easily passes over into it. Many forms of music, dancing, dress, and decoration, implying imitation through action, assume elemental qualities of the drama. Nor is it too much to affirm that however emphatic artists may be to-day, that art is to be practiced for art's sake, the origins of art, as the term implies, were distinctly practical. Every art was originally practiced to obtain some practical end, and required for its transmission the intervention of education. It is evident, for instance, that dancing, music, painting in earlier stages, constantly had religious purposes before them, and some of the greatest efforts of human art have been produced under the religious impulse. The drama in Greece arose out of the connected worship of Dionysus, Bacchus, Apollo, and Demeter. Even in the time of Pericles, the plays were acted at the festival of Dionysus. The dramatist had still to provide a satyric drama, in which the chorus was composed of the attendants of Dionysus. But the spirit of the drama of Æschylus, Sophocles, and Euripides rose to the highest topics — to the relations of gods and men, and the fate or destiny that ruled supreme over both gods and men. And in the Golden Age of Athens, it was the great desire of Pericles to throw open to all the people the supreme pleasures of the highest art. Accordingly, since the arrangements of the Athenian theater required a fee for admission, Pericles distributed out of the public funds the amount to each person (who needed the gift) to enable him to attend the theater at the feast of the Dionysia. The theater thus became a national educational institution, and an exceedingly powerful one. It has been said the Greeks were a nation of actors. Boys recited Homer, or Æschylus, or Euripides, and gave free play to gestures and delivery of speech, and the frequent dramatic representations served as models. The boys were, as Plato feared in the *Republic*, likely to become vulgarized by the realism of their

dramatic methods. He was keenly alive to the educational value of the drama. He realizes that a boy gradually *becomes* the thing he imitates, for better or worse, and he therefore insists that in all artistic pursuits the boy must only be given free scope for that which is calculated to draw out the best in human nature. Imitation in which impersonation is involved, where the reader, and, still more, the actor, identifies himself with the character represented, *i.e.* precisely what is meant by the dramatic, is, for Plato, so vivid a form of experience that it must be restricted to such subject matter, and such types of characters, as make for the betterment of the human soul. It is this extremely vivid appreciation of the educative aspect of the drama that gave rise to the function of the much-challenged censor. The drama was thus recognized as having an absorbingly important educational aspect in classical Greece.

Amongst the Romans, in the celebration of the festivals, the theater ranked next in general popularity to the chariot race and the gladiatorial contests. It is said that under Constantius 101 days in the year were devoted to *ludi scenici*. So powerful was the stage that Trajan boasted that theatrical displays controlled Rome. The stage was, indeed, degenerate, and presented chiefly farce and pantomime, and sank to infamous immorality. But the educative influence for good as well as for evil was even then undoubted. It is said that Arius had intended, at one time, to set up a Christian theater to supersede the loose spectacular entertainments of the decadent stage.

Through the Middle Ages, the regular drama of tragedy and comedy was obscured and gave way, predominantly, to other forms of entertainment, in which, however, the dramatic instinct was not lacking. The dramatic element was represented by minstrelsy of various kinds, in satisfying the "deep-lying instincts of the folk." And through village festivals the dramatic necessarily showed itself, until there were developed the festival plays, with many secondary dramatic forms.

But apart from these popular modes of self-expression, there are traces of the drama as a consciously educative force. In the first century A.D., Publilius Syrus composed his *Mimes*, and though the ethical element was decadent in the early centuries A.D. of the Roman drama, Syrus oftentimes gave forth *sententia* which were esteemed throughout the Middle Ages and onwards into the seventeenth century. In the fourth century A.D., Ausonius (*q.v.*), a schoolmaster of Bordeaux, wrote the *Ludus Septem Sapientum*. This consists of a series of recitations for each of the "seven wise men." It should be remembered that in 1659 Charles Hoole compiled a textbook for young pupils, which contained (along with Cato's distichs *De Moribus*) both the "Excellent sayings of the Seven Wise Men of Greece" and Publilius Syrus' *Stage Verses*, or Seneca's *Proverbs* (both

in Latin and English) "whereby little children may understandingly learn the rules of Common Behaviour," showing a recurrence to the old Roman drama for maxims of edification. In the tenth century A.D. Hroswitha, the Benedictine Abbess of Gandersheim in Eastphalian Saxony, wrote religious and moral plays to replace the comedies of Terence, evidently recognizing the educative power of the drama. After the Norman Conquest there are from time to time notices of the monastic literary drama, *i.e.* plays founded upon the classical models, but with Christian subject matter. Thus at Dunstable in 1110 there was a play acted by scholars in honor of St. Catharine. From 1170 to 1182 were acted a series of saints' plays mentioned by William Fitzstephen. Popular church festivals, sometimes assimilating pagan methods and material, together with survivals of the popular ancient dance and song, gave impetus to dramatic development. Thus the feast of the Innocents was associated with the celebration of the election of the Boy Bishop (*q.v.*), elected by his fellow choir-boys on the feast of St. Nicholas, the patron saint of children. With this celebration sprang up dramatic performances, and thence probably the play acting of chapel boys and schoolboy companies of actors.

In the later medieval period, schoolboys from the numerous chantry and other schools literally played important parts. In the service of the Church, at which they attended and assisted, the whole symbolic, mystical service had the dramatic element, exemplified in alternating song and visible action. The dramatic "mystery" was thus developed from the church liturgical service. The "mystery" was thus an active dramatic form of presentation of the scriptural stories, as the depicting on canvas and on glass and on pavement mosaics was the pictorial representation of the Christian story. The artistic forms of representation were thus in the hands of the clergy the surest forms of interesting the masses by visualization of Scripture story in an age before the printed book had made necessary the learning to read. Thus mysteries (Bible plays), miracles (saints' plays), and moralities (stories of personified moral qualities) were closely connected with the ecclesiastics and their pupils as the leaders of popular religious education. In the morality, the struggle between good and bad personified powers in the soul takes place for the possession of the whole man—a topic first discussed in Christian literature in the *Psychomachia* of Prudentius (*c.* 400 A.D.). Prudentius (*q.v.*) was a commonly read author in the schools—hence the idea of the morality found ready prepared ground in the school training. Schoolmasters were not infrequently the writers of moralities, *e.g.* Ulpian Fulwell, author of *Like Will to Like* (1568); and frequently the topics themselves were educational. Thus the *Interlude of the Nature of the Four Elements*, by John Rastell, son-in-law of Sir Thomas More,

introduces man prompted to study geography by *Natura naturata* and Studious Desire, and restrained by sensual Appetite and Ignorance. A play called the *Marriage of Wit and Science* was written by a Schoolmaster, John Redford by name. The hero Wit slays the monster Tediousness by his enthusiasm for study. In *All for Money*, Thomas Lupton (*c.* 1578) introduces the *personae dramatis*, Learning-with-money, Learning-without-money, Money-without-learning, Neither-Money-nor-learning (see *Cambridge History of English Literature*, Vol. V, p. 57). It is thus clear that if these *origines* of the drama are ascribed to ecclesiastics, schoolmasters also were closely connected with the writing of the dramas, and schoolboys with their acting.

In 1427 the twelve lost plays of Plautus were recovered, and, besides the opportunity thus given for the reading of those plays, their discovery suggested to aspiring Latinists the imitation of their Latinity, and the dramatic form. The fact that scholars conversed in Latin made the discovery of the Latin conversation of the newly found dramas of especial importance, as models for speaking and for imitation in composition. Ravisius Textor, while professor of rhetoric in the College of Navarre in Paris, wrote dialogues in Latin for his pupils to recite dramatically. Terence and Plautus were the authors especially studied by the young student, in the time of the Renaissance, so as to cull the phrases best suited for conversation. J. L. Vives, in 1531, says "Terence is of importance for daily conversation." The colloquy was the daily study of the little boys for Latin speaking, and the older boys of the school were required to act scenes from the Latin dramatists. Eventually a school play became an institution for state occasions, and even a regular part of the time-table. Early in the sixteenth century the school play was established in Germany, Holland, and England. As to Germany, Professor Herford says, "The *Rath* not unfrequently contributed to the often considerable cost of school-plays and at Strassburg gave them an appointed income from the municipal budget." The early Dutch school dramatists gave rise to the various treatments of the gospel parable of the Prodigal Son.

The most famous plays founded on this parable were the *Acolastus* of William Gnapheus, (1528), the *Rebeller* (1535) of Macropedius, and the *Studentes* of Christopher Stymmelius (1549). (See PALSgrave, JOHN, English translator of Gnapheus' *Acolastus*.) Other scriptural subjects gave rise to plays directly based on the Roman dramatists. During the Reformation period, the drama became an instrument for presenting Protestant views, *e.g.* in the *Pam-machius* of Kirchmayer, written in 1538 and translated into English by John Bale. In England, the use of biblical and didactic subject matter was quite as characteristic of the play writers, as it was abroad, and schoolmasters were quite as much to the front. Not only

were there translators of foreign biblical plays, such as John Palsgrave and John Bale, but English schoolmasters composed plays for their own pupils to act.

Professor Schelling (*Elizabethan Drama*, Vol. 1, p. 94) draws attention to the fact that the earliest English playwrights were schoolmasters or courtiers, and amongst the schoolmaster pioneers of the Elizabethan drama he names Radclif, Rightwise, Palsgrave, and Udall. Ralph Radclif (1519-1555) is known from the reference to him by John Bale in the *Catalogus Britannicæ Scriptorum* (1557-1559). He held his school in the disused Carmelite Monastery in Hitchin (Hertfordshire). He used as theater the refectory of the old monastery, and trained his pupils to act the plays he wrote, with a view to securing good enunciation and freedom of manners in the pupils. In addition, Radclif wished to make known the Scriptures by some of his dramas, dealing with such subjects as *The Delivery of Susannah*, *Job's Sufferings*, *The Burning of Sodom*, *Jonas*, *The Fortitude of Judith*. Some of his plays show the introduction of strong religious bias, e.g. the *De Joannis Huss Bohemici nati condemnatione*. John Rightwise, son-in-law of William Lily, and his successor in the headmastership of St. Paul's School, wrote a Latin tragedy, *Dido*, which in 1532 was witnessed by Cardinal Wolsey, — though a Latin morality ridiculing Luther and his wife had been acted before King Henry VIII by the St. Paul's schoolboys in 1527. It is supposed that Nicholas Udall's *Roister-Doister* was written for the Eton College boys between 1534 and 1541. This play, founded upon the *Miles Gloriosus* of Plautus, is the starting point of the modern English comedy, and comes thus direct from a schoolmaster author, and was first acted by schoolboys.

We have thus seen that the drama at its best in ancient Greece and Rome had popular educational aspects from the ethical point of view, and in the Middle Ages was used for popular education in religion, while with the Renaissance, the drama actually entered the schools, and was used as an avowed educational instrument in the school. The opinion of Lord Bacon on the educative value of the drama has an especial interest, as coming from so great a contemporary of Shakespeare. It occurs in *De Augmentis Scientiarum* (Bk. II, ch. xiii), 1623. "In modern states," says Bacon, "play-acting is esteemed but as a toy, except when it is too satirical and biting; yet among the ancients it was used as a means of educating men's minds to virtue," and in Bk. VI, ch. iv, occurs the following statement on the *raison d'être* of the relation of the drama to school education in the view of the early part of the seventeenth century. After claiming that the Jesuits attach importance to school acting, and in Bacon's opinion "therein judging (as I think) well. It is a thing indeed, if practised professionally, of low repute; but if it be made a part of disci-

pline, it is of excellent use. I mean stage-playing; an art which strengthens the memory, regulates the tone and effect of the voice and pronunciation, teaches a decent carriage of the countenance and gesture, gives not a little assurance, and accustoms young men to bear being looked at."

The use of the drama for polemical purposes is closely bound up with the educational motive, as is seen in the Reformation school dramas. But in the later sixteenth and seventeenth centuries, with the development of the acting of the Elizabethan drama in recognized public theaters, the school drama was differentiated as a pedagogical institution. Westminster School is worthy of note in this connection, since the school plays, especially those of Terence, with Latin prologue and epilogue dilating humorously on the events of the day, have gone on regularly, and continue still to be rendered annually on the second Thursday in December, and the Monday before and after that day. This is in accordance with the statutes of Queen Elizabeth (the school existed long before these statutes), c. 1560. Nicholas Udall, who was headmaster of Westminster before this date, viz. c. 1554-1556, had been headmaster of Eton, and had had his *Roister-Doister* performed by Eton boys before 1541. Even before writing this comedy, Udall had shown his interest in the ancient drama by translating *Flowers of Latin Speaking* from Terence, c. 1533.

Mr. John Sargeaunt, the historian of Westminster School, says the fact of having the annual play was no "special mark" of the school. "Acting was generally regarded as a necessary part of education. There was perhaps no school of note which did not frequently put upon the stage both the dramas of Plautus and Terence, and those dull Latin comedies of which the age was so prolific." Mr. Sargeaunt notes that "after the Puritan epoch, the Westminster play was the sole survivor, and this survival is to be explained by the fact that by the statutes, penalties were to be inflicted for any omission at Christmas of a Latin play from the Westminster schoolboys and an English play by the choir-boys." Dean Nowell was headmaster of Westminster school before the Royal Statutes of 1560, and it was he who in 1513 "brought in the comedies of Terence for the better learning of the pure Roman style." Shrewsbury school, which Camden states had more scholars than any "one school in England," had its dramatic performances, and Thomas Churchyard, the Salopian poet, states that at Ashton's play a beholder "might well have seen there twentie thousand men." It is recorded that in 1568 "at Whitsuntide was a notable stage play at Shrewsbury, which lasted all the holidays, unto the which came great numbers of people, of noblemen and others, the which was praised greatly, and the chief author thereof was one Master Ashton, being the head schoolmaster of

the Free school there, a godly and learned man, who took marvellous great pains therein." Thomas Ashton's first play was acted in 1561, and in the Ordinances of 1578 (of which Ashton was the chief author) the regulation was made that on every Thursday the highest form should " declaim and play one Act of a Comedy." At Sandwich Grammar School, Kent, in 1580, the statutes required " at every Christmas time, if the master do think meet, to have one comedy or tragedy of chaste matters in Latin to be played, the parts to be divided to as many scholars as may be, and to be learned at vacant times." In 1612 John Brinsley in the *Lulus Literarius* is urgent that Terence, and then the plays of the *Terentius Christianus* of Cornelius Schonæus, should be gone over by scholars, for Latin speaking; and that these plays were read widely in the English schools is indicated by the number of editions, printed in London, as well as abroad. The edition of 1635, printed at Cambridge, states explicitly that it is *ad usum scholarum seorsum excusa*.

Oliver Cromwell in the early sixteen hundreds entered the Huntingdon grammar school, where Dr. Thomas Beard was the headmaster. Dr. Beard had written classical comedies, and was the author of the *Theatre of God's Judgments*, a graphic account of examples of the justice of God against notorious sinners. Heath, an early biographer of Cromwell, says: " It happened (as it was then generally the custom in all great free schools) . . . that Oliver Cromwell, as a confident youth, was named to act the part of Tactus, the sense of feeling, in a play called the *Five Senses* (or *Lingua*). These school plays were sometimes celebrations in which the town took a great interest, as, e.g. at Shrewsbury. In the Town Records of Southampton, in 1576, it is noticed: " Paid to Mr. Adrian [Saravia] for his charges and pains in his tragedie, by consent xxs." Plays were acted in the Southampton grammar school until a comparatively recent period.

Warton mentions (Vol. III, p. 309, ed. Hazlitt) a comedy written by William Hawkins, headmaster of Hadleigh grammar school in Suffolk, and acted by his scholars on Shrove Tuesday, 1626 — entitled *Apollo Shroving*. This is a genuine school play, with twenty-three characters, including such as " a young scholar," a " book-bearer," " a diligent student," a " perplexed scholar," a " young fresh scholar," a " truant," a " cockering mother," a " lazy drone," and " Captain Compliment, a teacher of gestures and fashions."

The reference in Ben Jonson's *Staple of News* (1625) (Act III, Scene 2) perhaps best brings home the close connection of the drama and education. Speaking of schoolmasters, Jonson says: " They make all their scholars play-boys! Is it not a fine sight to see all our children made interluders? Do we pay our money for this? We send them to learn their grammar and their Terence, and they learn their

play-books. . . . I hope Zeal-of-the-land Busy and my gossip Rabbi Troubletruth will start up and see we have painful good ministers to keep school and catechise our youth, and not to teach 'em to speak plays and act fables of false news."

The employment of boys in the old sacred dramas, the mysteries and moralities, has already been mentioned. The boys of the chantry schools and song schools were often acolytes who served at mass, who were readily available for acting purposes. The Children of the Chapel Royal in London are traced back in the records to 1506. St. Paul's boys acted in 1528 (see E. K. Chambers, *Medieval Drama*, Vol. II, p. 193). These boys became a recognized company of play actors under the patronage of Queen Elizabeth; so did the Children of the Choir School of St. Paul's. Professor Schelling points out that apart from these professional companies of play actors the boys of Merchant Taylors' School acted so much that the headmaster, Richard Mulcaster (1561-1586), must have been a theatrical manager; and we are told that he wrote six Latin plays.

In 1642 came the closing of the theaters in England by the Long Parliament. They were not reopened till the Restoration. The play thus by reflection from the national attitude toward the drama, fell into desuetude as a public institution in the schools, and was not generally resumed, when the theaters were reopened in Charles II's reign. One reason no doubt was that Latin ceased to be taught in England as a spoken language; gradually French began to take its place as an international language of travel, diplomacy, and conversation, and the colloquial Latin, for which Plautus, Terence, and original Latin dramas had been introduced, learned by heart and acted, became unnecessary. In the eighteenth century the well-known Dr. Samuel Parr, after he left Harrow, started a private school at Stanmore, near to Harrow, in 1771, and trained his pupils to perform the Greek plays of *Ædipus Tyrannus* and the *Trachiniae* of Sophocles. Dr. Richard Valpy, headmaster of Reading School (1790-1802), had four plays of Plautus acted in the school, and six plays of Shakespeare. Dr. Valpy wrote in his Preface to his Poems a defense of school plays. In the nineteenth century the two English public schools outstanding for their school plays were, of course, Westminster, which continues its cycle of the *Andria*, *Thormio*, and *Adelphi* of Terence, and the *Trinummus* of Plautus; and Bradfield College, Berkshire, which has produced a long series of Greek plays. There have been other representations, at different schools, but these two schools continue regularly to present classical plays.

Though the drama was suppressed in England in 1642, it continued unchecked abroad, and the great educationist, J. A. Comenius, is thus introduced in this connection in Morhof's

*Polyhistor* (written in Latin): "as in the republic comedy in the *School of the People*, so for children, schooling can be advanced by the acting of plays. Much more firmly," he goes on, "do the examples of illustrious men stick in the mind through representation by acting. Even moral and civil precepts can thus be made to appeal to youth." So Comenius advocated teaching the history of the philosophers by plays, and as an example wrote *Diogenes Cynicus* as a school play. Moreover, he turned his *Janna Linguarum* into a comic play (1657). "So we see," adds Morhof, "that schoolmasters have not merely approved school-plays, they have also enjoined them." In his preface to the Latin play *Encyclopadia Viva*, and *Janna Linguarum praxis comica*, Comenius, a strong Puritan, says, "Theologians urge their objections against us (schoolmasters) in vain. They wish to drive comedy from the state as well as the schools, because they object to the subject matter put on the stage. The answer is, to only put edifying matter into school-plays. There are seven conditions to be satisfied in a school-play. There must be movement, spontaneity, sociability, friendly emulation, distinct rules, good example, and relaxation of mind." To promote freedom and spontaneity Comenius suggests that the boys should be encouraged to throw into the Latin play any suitable *adagia* and *flosculi* which occur to them.

Even after the school drama had subsided in England, its influence survived. Thus in 1678, Samuel Shaw of Ashby-de-la-Zouch grammar school, wrote in drama form an appeal in favor of rhetoric. It is called *Words made Visible; or Rhetorica Accommodated to the Lives and Manners of Men. Represented in a country school for the entertainment and edification of the Spectators*. In 1737, John Holmes, headmaster of the Holt Grammar School, Norfolk, made history teaching interesting by employing the dramatic instincts of the boys in carrying out his pedagogic views. He wrote an account in *The History of England, being a compendium adapted to the capacities and Memories of Youth at School. Performed by the Gentlemen of the Publick Grammar School at Holt in Norfolk at their Christmas Breaking-up in 1735.*"

The twentieth century seems likely to witness a renaissance of the employment of the dramatic impulse founded on the psychology of the instinctive nature of the child. For this appears to be the right line of the development of the imitative impulse, such as we see in the first names the child applies to objects round about him, e.g. bow-wow, puff-puff, etc. The child's play is really drama, as may be seen in the elementary forms, e.g. in Bo-peep. The child's play involves the dramatic also in its instinct of constructiveness. This is manifest even in the play of conscious self-deception — which often in child's play is a mental construction to take himself in — "make believe." There is a tendency in children to turn all ex-

periences into narrative, joined with dramatic form, e.g. in baby games with the toes and fingers, such as: —

Narrative with Action	}	This little pig went to market.
		This little pig stayed at home.
		This little pig had all the bread and butter.
		This had none.
		This cried, "Wee, wee, wee!"

Many of the ring games and group games of children are dramatic lyrics, e.g. developed into games: *Round the Mulberry Bush*, *Here come three Jolly Sailors*, *I'm on the King's Ground*, etc. Froebel uses this basis of the dramatic lyric in his *Mutter- und Koselieder*, — and thus trains observation of objects and their properties by means of the dramatic element. Gradually, every department of the environment is imaginatively explored dramatically by the child, e.g. in "playing school," "playing house," "playing soldiers." More complicated or more distant ideas become familiar, and observation is quickened — by "playing animals," or, say, "Red Indians." The crucial element in the drama, of impersonation comes within the child's scope very early. For instance, kindergarten school children learning reading and phonetics at the same time have imagined the letters making their own appropriate sounds, personifying them, thus ;

A says, *ah, ah, ah,*  
 B says *bb, bb, bb,*  
 A and B say, *ba, ba, ba.*

With the elements of the dramatic so close and familiar to the child, in the kindergarten methods, the tendency now is to apply the dramatic method along with other methods still further in the school age. Thus, in history, the pupils impersonate the chief characters of an era; or, on a larger scale, we find municipalities in historic towns arranging for magnificent historical pageants. In geography children are led to imagine themselves taking a journey between such and such places, and to state what they would expect to see. In arithmetic examples are given which make use of suppositions implying the dramatic, such as requiring the child to imagine himself a merchant drawing up bills of parcels, or a banker in matters of interest and discounting of bills. In literature, recitation with accurate pronunciation, right intonation, and appropriate gesture has always held its place in the school. The whole art of rhetoric is founded on the idea of dramatic effect. Even in the problems of a right social and moral attitude, the dramatic form has played its part, e.g. in the Renaissance School of Valentine Trotzenorf (c. 1531), and in modern times, in Rowland Hill's School at Hazelwood, where in both schools a system of government was established by the boys themselves through their elected officers acting as courts of justice — in relation to the necessary discipline of the school.

There is, further, a return to the old position

of the drama as an educative force by dramatists themselves. Mr. Bernard Shaw says: "The theatre is a place which people can only endure when they forget themselves, that is, when their attention is entirely captured, their interest thoroughly roused, their sympathies raised to the eagerest readiness, and their selfishness utterly annihilated." That the school and the drama should cooperate on terms such as these, no one would deny, and the time may come when it will be the business of the school to prepare pupils for the due enjoyment of the best things in life, in music, in painting, in architecture, and in the drama. But one element which the drama seems to present more clearly, perhaps, than any other art, cannot be dispensed with in any liberal education, viz. that of training the sympathetic imagination, so one may be able to throw himself into another person's position, and in imagination to see the "other person's" point of view. For this reason the dramatic, in some form or other, must be recognized as a necessary basis for the teaching of history, literature, and social relations.

**DRAMATIZATION, METHOD OF.** — The method of having one or more children act out a human situation or story in the presence of the class in order to vivify the subject studied.

See the separate subjects of the curriculum; also DRAMA AND EDUCATION; OBJECTIVE METHODS.

**DRAPER, HENRY** (1837-1882). — A scientist, who graduated from New York University in 1858, and was several years a professor in that institution. He was the author of a textbook on chemistry and numerous scientific works.

W. S. M.

**DRAPER, JOHN WILLIAM** (1811-1882). — Scientist and educator, born in England, and graduated from the University of Pennsyl-

vania in 1836. He was for two years professor in Hampden-Sidney College, and for forty-four years (1838-1882) professor in New York University. He made important discoveries in physical science, and was the author of textbooks in chemistry, natural philosophy, and physiology, as well as of many scientific works. His *History of the Intellectual Development of Europe* was one of the best historic accounts of the achievements of science. (For portrait, see opp. p. 255.)

W. S. M.

**DRAWING. — History.** — In 1767 Louis XV issued letters patent establishing a Free Royal School of Drawing in Paris, to promote manufactures and commerce in France. During the next hundred years other institutions of similar character were established in European countries, and the Maryland Institute was founded in the United States. Drawing was required in the public schools of Bavaria in 1811, and of Austria in 1850; but the more comprehensive and systematic instruction in art for the advancement of industry began in Great Britain with the founding of the South Kensington Museum in 1852.

Notwithstanding the efforts of William Bentley Fowle (Boston, 1820-1830), Horace Mann (Boston, 1837-1848), Rembrandt Peale (Philadelphia, 1840-1844), and Henry Barnard (Hartford, 1838-1867), drawing did not become firmly established as a required study in public schools until 1870, when the Massachusetts Legislature approved an act including drawing among the branches of learning to be taught in the public schools of the state. Between 1870 and 1907 drawing was made one of the studies required in public schools by act of legislature in twelve states, and became an approved study, promoted by official action, in thirty-one others. It was made compulsory in the public schools of Switzerland in 1874, and of France in 1878.

**Theory.** — The reasons for requiring drawing in the public schools are mainly the following: (1) Drawing is a language of form. By means of it the contours and colors of all visible objects, their structure and enrichment, and their interrelations in space may be defined and displayed. It is therefore the graphic recorder of scientific fact, the primary means of expression in the constructive and decorative arts, and the chief medium of the artist in making known his visions of beauty; hence the ability to understand and to make use of this language is of value to all. (2) The practice of drawing promotes (a) close observation, thus insuring clear mental images, the material of thought; (b) muscular control, or skill of hand, a prerequisite in the practice of any craft; (c) a knowledge of the elements of beauty, in nature and art, the basis of design, and the ground of intelligent appreciation and taste. Hence, drawing should be practiced by all. (3) The study of drawing opens to the mind the wealth

of human treasure in the form of architecture, sculpture, painting, and the various handicrafts, through which man has expressed his ideals and aspirations, and leads to a keener appreciation of nature as an inspiration to art, thus vastly increasing the pleasure and the significance of life. It should therefore be free to all.

**Subject Matter.**— In Berlin, Germany, as early as 1844, geometrical drawing, drawing in outline from models, and freehand sketching were included in the course in drawing; but the work usually done by pupils both in Europe and in the United States, until about 1880, consisted chiefly of drawing geometric designs from dictation, copying freehand from the flat outlines of objects and historic ornament, and working problems in geometry and mechanical perspective with instruments. The courses of study in the elementary grades in the United States now generally include (1) nature drawing, (2) illustration, (3) object drawing, (4) design, and (5) construction, or the making of objects, the logical resultant of drawing and the test of its character. In secondary schools these topics are commonly classified as freehand drawing, including something of the theory of perspective and the history of art; mechanical drawing, including geometry, projection, development, and applications in the realm of architecture and mechanics; and design, including lettering, adaptation of natural forms, coloring, etc., with applications in dress and house furnishing. The European courses have been modified greatly during recent years, through the influence of American ideals.

**Current Practice.**— *Nature Drawing.*— From the outset pupils are encouraged to furnish their own specimens, to prune them, to pose them for the most effective view, and to draw them with colored crayon or water color, directly, without sketching first in pencil. Attention is given successively to the main lines of growth, to the branching, to the relative proportions of parts, to the effects of foreshortening as seen in leaves and flowers, to the details of structure, at the joints, in leaf scars, etc., and lastly to the total beauty of effect. At first only characteristic local color is considered, then the natural gradations of color, and lastly the play of light and shade and the resulting modifications of the local color. Emphasis is laid upon the arrangement of the drawing within its frame, and upon the proper size, color, and value of a mount for the drawing. The nature drawing throughout is related to the nature study, and furnishes material for use in design.

*Illustration.*— From the beginning pupils are encouraged to express freely, by means of drawing, their ideas of objects, their memories of experiences, and the images called up by spoken or written words. Memory drawings of incidents, games, sports, occupations, are followed by drawings illustrating Mother Goose, fairy stories, myths, legends, historical stories,

etc. And along with this practice goes the observation and record of the sky and the earth as affected by the changes of day and night, of the weather and of the seasons. In this work the emphasis is not primarily upon accuracy of delineation, but rather upon the idea embodied, the spirit with which the story is told, the effect produced by the grouping of principal objects and accessories. The aim is free graphic expression. In the middle and upper elementary grade this passes into the applications of object drawing, and is strengthened by the study of book illustrations and pictorial art.

*Object Drawing.*— In the lower grades this phase of drawing is the logical outcome of free illustration. The pupils begin to give closer attention to the forms of objects, to their toys, and other things of special interest to children, including pets and the common birds and animals. They then begin to study common objects more critically, first for their proportions and contours as revealed in silhouette; then as to their apparent shapes as seen foreshortened and otherwise modified by their position in relation to the eye. The usual order of difficulties to be mastered is (a) the representation of solidity as seen in spherical objects, (b) of foreshortening as seen in hemispherical and cylindrical objects, (c) of convergence as seen in rectilinear objects in upright positions, (d) of foreshortening and convergence as seen in objects of mixed character and in combination. These are represented first in mass, by means of colored crayon and brush, and later in outline by means of the pencil, and lastly in light and shade and color by means of charcoal and water color. This work merges with illustration and the study of pictorial art in the upper grades.

*Design.*— Design begins in the lowest grades, with the study of color and the application of color in producing the simplest sorts of pattern, and with the proper placing of the nature drawings within margin lines. Later simple natural forms, animals, birds, insects, leaves, and flowers, are freely repeated to form borders and surface patterns for school papers, etc. The study of the principles of design, rhythm, balance, and harmony, both in form and color, begins in the intermediate grades, and continues throughout the high school; all the designs produced being either abstract (as illustrations of principles) or applied in common objects of interest to the pupils themselves. The applications involve some knowledge of such processes as weaving, embroidery, stenciling, block printing, leather working, the cutting and manipulation of sheet metal, and the adaptation of plant and other forms to given conditions. Standards of excellence in design are found in historic and modern examples of handicraft. These are studied critically in the light of the principles of design. (See DESIGN.)

*Construction.*— The use of such implements as the scissors, the ruler, the knife, the compasses, and the common thread-working,

leather-working, wood-working, and metal-working tools is acquired by constant practice, beginning with the scissors in the lowest grades. Paper folding and cutting, the preparation of papers of the right size for school work, the making of paper furniture, booklets, envelopes, toys, illustrative objects required in language and historical stories, is followed in the intermediate and upper grades by the working out in appropriate materials of designs for all sorts of objects useful in school or home life, or in the social activities of the time, — maps and apparatus for illustrative purposes, booklets, table mats, draperies, pillows, boxes, bookracks, articles of clothing, pocketbooks, jewelry, articles useful in outdoor sports, furniture, and any other object of real value. The aim in this work is, first, practical experience in design and in the processes of construction; technical excellence is of increasing importance with every succeeding grade.

In the best schools these various lines of work are not separated by hard and fast lines, nor are they pursued arbitrarily without reference to local conditions. The season of the year, holidays and festivals, the other school studies, the dominant interests of the community, as well as of the children, are all considered in the ordering of the program. The aim is to make drawing a familiar means of expression, to enable the pupils to acquire the habit of clear visualizing, of thinking to some purpose, and of working with skill and taste; and to lead them to see that art which has enriched the lives of men in the past may enrich and glorify everything now, in every grade of school, and in every phase of the life that may follow. H. T. B.

**DRAWING, HYGIENE OF.** — The essential aim in drawing from the hygienic point of view is the development of a normal habit of expressing thought, and the avoidance of injury to health from this occupation. Hence the demands of hygiene are both positive and negative, — on the one hand, training in drawing

as a normal form of reaction, on the other, the avoiding of all conditions detrimental to health. On the negative side very much the same hygienic rules apply as in writing; but as drawing is a means of expression that may naturally come before writing, and as it has some peculiar aspects, the hygiene of the subject demands separate consideration. Drawing, according to Baginsky, is an especially dangerous occupation for young children on account of the strain of the eyes likely to occur and the strong tendency to malpositions.

The drawing room should be so arranged that the light comes from the north, or if it is not used continuously, it should be so situated that there is no direct sunlight during the hours when this occupation is carried on. It may well be placed on the top story where conditions are favorable and provided with light from above. If not, the drawing table should be arranged so that the light comes from the left. There should be an abundance of light, the total window surface being equal to at least one fifth of the floor surface. Drawing should be omitted when the light is insufficient, and drawing by artificial light should be avoided; if necessary, there should be an abundance of diffused light and individual lamps at each desk. The drawing table should be constructed in such a way that pupils can work standing. The tables should be ample in size, not less than two and one half feet wide, and of different heights to accommodate pupils of different size, or else pieces of plank should be supplied which can be used by the smaller children. If the ordinary school seats and desks are used, then they should be adjustable and adapted to the heights of the pupils.

In drawing, the position of the body and the hands should be correct, long pencils should be used, the eyes should be kept at the proper distance from the table or the blackboard, as a rule about twelve to fourteen inches. The work in drawing should be broken by opportunities for looking at things at a distance. In general the well-accepted rules for the hygiene of vision should be regarded. The pupils should be warned against putting their fingers in their mouths when stained with colors. Care must be exercised in the use of thumb tacks, etc. Large pencils or crayons and suitable paper form the necessary materials for drawing. If blackboards are used, they should be of the best slate. Cleanliness should be especially emphasized. When colored chalk is used, care should be taken to avoid that which contains arsenic. Drawing books are no longer used by the best teachers. If used, they should not contain fine work or any work likely to be injurious to the eyes. The methods of drawing containing a network of lines should be condemned. The so-called Stuhlmann method, which consists of drawing by the aid of a network of fine lines, points, and the like was condemned many years ago by German oculists,

and forbidden by the Bavarian Ministry in 1883.

Tests of vision should be made before instruction in drawing is begun. Color blindness is frequent among children, at least among boys. Jeffreys reported in 1880 on an investigation of 27,927 school children for color blindness. He found 4.20 per cent color blindness among the boys, and .066 per cent among the girls. Recent investigations by Dr. Hayes show a considerably larger percentage among girl students at Mount Holyoke College. The tests for vision should include a test for color blindness by the use of the Holmgren worsteds or Nagel card tests.

A correct posture should be emphasized. Baginsky thinks it more difficult to get a correct posture in the drawing class than in writing, because the children are so much interested in drawing. This question has been made the subject of special consideration in Germany. The teachers of drawing of the Berlin Teachers' Association, with the advice of eminent physicians, formulated the following rules some years ago: (1) The position of the upper part of the body should be natural and without strain, as free and erect as possible. The head should be inclined only a little and toward the side, and bent forward only very slightly. Both shoulders should remain at equal height. The line connecting them should be parallel to the edge of the table. The legs should be kept apart. The lower part of the legs should be kept vertical, the feet squarely on the soles. (2) The drawing surface should be placed directly in front of the medial line of the pupil. (3) The left forearm should lie on the table, and can be stretched forward, when necessary, until the lower part of the upper arm is on the surface of the table. But the forearm should not be used as a support for the upper part of the body. The left hand should tightly hold the drawing surface. (4) The right forearm should be so placed that free movement is possible. It should neither be placed firmly against the body, nor serve as a support for the upper part of the body. (5) The right hand should be supported lightly on the little finger. The hand joint should not touch the drawing surface, and the hand should never cover the line to be drawn.

Drawing, if rightly taught and of the right kind, may be begun at an early age, but it should be large and free and continued for only a short period, not more than fifteen minutes in the kindergarten and early grades, and should begin with the large curves that are easily made on account of the structure of the arm, and should consist largely of whole arm movements such as are naturally employed by the child when scribbling. Drawing should be a valuable means of healthful training: first by developing habits of cleanliness, and second by training to healthful modes of expressing thought. The importance of cleanliness should

be emphasized. Great care should be taken not only to have the drawing room clean, but to keep all models, illustrations, and the like, clean, and to avoid dust from pencils, chalk, etc.

From a broader point of view, drawing as artistic expression represents a form of activity positively in the interest of health. It is one of the oldest and most universal forms of speech. Modern psychiatry emphasizes the importance to health of normal habits of expressing thought and feeling. Any form of artistic expression is a relief to intense feeling, and a prophylactic against morbid emotion. Some, like Goethe, find relief in writing; others in song; others in the different plastic arts, and so on. Dr. Scott lays stress on the function of art as a remedy for morbid fears. Frequently, he points out, the thing which at one time children are most afraid of they come in time to love. "And in my opinion," he writes, "there is not anything which will more conduce to remove those morbid fears from the constitution than allowing this emotion to run out in motor expressions, in expressions in artistic form." The positive side of the hygiene of drawing can be properly appreciated only by considering the significance of this form of motor activity as a means of artistic expression. There is a fundamental impulse in human beings to express feeling in activity. Art originates in the need for the expression of feeling. It is based on innate impulse. The significance of drawing as a means of expressing thought and feeling is clearly shown by the spontaneous drawings of children, the drawings of primitive people, and of the insane. It is a form of activity that is self-sufficient, worth while for its own sake. The product has also a social significance. An individual always considers his work in relation to other individuals. An imaginary audience is always present. This is represented, if in no other way, by the individual's critical attitude toward his own work. Thus drawing (1) is a form of normal reaction to feeling; (2) it gives the satisfaction that comes from productive activity and social expression; and (3) it develops an interest in art by making imitation possible. From the ordinary point of view of hygiene this is vague, but the psychiatrist, and the teacher who appreciates the importance of a normal life of feeling, of the satisfaction from productive activity, and of the balance that results from culture interests, cannot fail to see the positive hygienic significance of this and similar forms of artistic expression. W. H. B.

**DRAWING ROOM IN THE SCHOOL BUILDING.** — See ARCHITECTURE, SCHOOL.

**DREAMS, AND DREAM STATES.** — The psychological interest in dreams centers about the contrast of their thought progression to the procedure in the normal waking state. Dreaming thus presents the most illuminating yet familiar type of mental departure from purposive thought. The central contrast lies in the loss of control, the abeyance of the directive guidance. Yet such direction in the service of a logically intentioned end is in itself so gradual and artificial an achievement, that the quality of dreams may be regarded as the more natural, at all events the more spontaneous expression. Clearly a large part of ordinary thinking is affiliated to the more playful reverie that dominates dreaming. Dreams thus reflect, though distortedly, something of the deeper individual qualities, and in their freedom from intentional interference may furnish a clew, especially in abnormal cases, to the suppressed psychic entanglements and obstructions that surreptitiously prey upon the waking consciousness. A further contrast between dreaming and waking lies in the withdrawal from the world of outer stimulation, the larger dependence upon inner feeling and contemplation, and the introspective elaboration of the mind's more personal imaginings. In any view, the content of dreaming must present a large community of origin and interest with the reservoir from which the more alert and purposive activities draw their resources. This relation is well illustrated in the frequency with which matters of deep concern and recent interest reappear in dreams. Yet this community is quite compatible with a certain antagonism, in accordance with which concerns that are driven out from the waking activities by the very dominance of the consciously maintained interests rise to the dreaming consciousness when the rival occupations are in abeyance. The principle is aptly illustrated in the contrast of the outward and the inward directed sense-feelings. The daylight activities of the ear and the eye absorb the mind's interests and drown the murmur of the body feelings — the tensions, fatigues, position cramps and minor aches — which, with the shutting out of the objective world, rise to clearer expression and in turn furnish the emotional tone of the dream content. The nightmare of indigestion is but a drastic illustration of the principle. Concordantly with this view the sensory materials

of the dream movement are classified as *presentative* and *representative*, the former referring to the sense activities that are still alert enough in the suppressed consciousness of the dream state to assert themselves, while the latter contribute the reverberations of recent experiences and the development thereof. When the carrying of a lighted candle through a room in which the sleeper lies induces a dream of fire, or the rustling of a window shade a dream of rumbling thunder, the actual sensations reach the sleeper without waking him, and form presentative elements; yet more characteristic are the direct bodily stimulations (such as the contact of a hot-water bottle inducing a dream of walking over burning lava, the tickling of a sleeper's nose resulting in a dream of wearing a mask, or the exposure to the perfume of eau-de-cologne giving rise to a dream of the Orient), which, equally presentative, yet appeal to the senses more intimately connected with the detached sensory consciousness of sleep.

Whatever the origin, whether more immediately from sensations still vibrant, or from the revived memory images, the constant characteristic of the dream action is to transform its material dramatically and often pictorially into a scene with more or less vivid setting, and therein combining with a distorted logic seemingly unrelated data from diverse sources. It is this playful reverie or dramatic romancing that characterizes the mental movement; and it is equally this that reappears in day-dreaming and in much of what is called thinking with a relaxed effort and an invitation or consent to let the thoughts wander with loose guidance. The association sequences thus emerging are individually characteristic, and the tendency to indulge in such romancing quite common, and in some temperaments dominant. The trait is clearly affiliated to the poetic tendency, to the actively imaginative mind that enables the artist to pursue his work in so far as he may succeed in setting in orderly arrangement the products of his partly directed reverie. Hence, last as first, the significance of dreams lies in their revelation of a characteristic factor of the total mentality.

The physiological as well as the psychological conditions of dreaming are closely related to the voluntary factor, the loss or retention of control, and equally related to the power to assimilate the impressions of the outer world. Being awake means to respond measurably to one's surroundings and to direct the thought movement. In the succumbing to an anæsthetic, the stage of diminishing consciousness is gauged by the waning of the power to command the muscles and to feel a stimulus; so similarly in the involuntary falling asleep, the loss of the erect posture of the head (which is a voluntary adjustment) may precede the complete insensibility to a spoken word. Since the more complete abeyance to these functions

normally involves such a depth of unconsciousness as to be either dreamless or too weak to arouse a recallable dream, it follows that dreaming is related to the lighter sleep introductory to or consequent upon the deeper stages of sleep.

All states involving a sharply limited consciousness and a distinct loss of direction of the stream of thought are allied to dreaming. Abstraction, absorption in idle reverie (the situation that arouses the offer of "a penny for your thoughts"), again, the more persistent ravings of delirium, the transitory visions of *hasheesh* or *mescal*, and, quite differently, the actions of the hypnotized subject are all abnormal through sacrifice — yet different varieties of sacrifice — of the full privileges of normal mental action. A characteristic problem is that of determining how far in such states a connection with the waking consciousness persists. The fact that we remember dreams is itself an evidence of such relations; the actual persistence of the dream into waking — similarly to a projected hallucination — is well established: the playing in and out of fact and fancy in *hasheesh* and other intoxication is characteristic; while in hypnosis and trances, the two sets of ideas and actions reveal the typical subconscious relations, whereby what is seemingly suppressed or forgotten to the one consciousness may by indirect appeal be reinstated in the other.

A further characteristic of dreams is their intimate relations to the emotional life; their feeling-tone seems more directive than their associative sequence. Hence mood, bodily condition, care, worry, depression, grief, excitement, contribute intimately to the movement, which the logical powers set to pictures or to words, with such dramatic sequence as they may command. From this aspect, again, dreams become related to the personal, the private, the half-acknowledged mental life, in which in spite of awaking control, and objective interests, the desires, hopes, and secret planning for the future — all closely centered about the personal welfare — reach inarticulate expression. It is this interpretation of dreaming that has furnished the motive to the works of Freud and others, who find in the records of psychic impairment (typically in hysterical and neurasthenic cases) that the tracing of dreams to their suppressed or detached origins in unfulfilled desires and longings, is itself a means of diagnosis, and, through their transformation into an explicit statement, a cathartic and curative measure. So also the analysis of normal dreams proceeds upon their interpretation as development of the less explicit desires that contribute intimately to our personal thinking. The view is the more consistent when applied to the deeper and more sustained dreaming efforts, and thus leaves room for the incidental, pictorial, reverberatory origin of the slighter dream episodes.

**DRESS OF SCHOOL CHILDREN.** — See CLOTHING OF SCHOOL CHILDREN.

**DRESSMAKING.** — See HOUSEHOLD ARTS.

**DREW THEOLOGICAL SEMINARY, MADISON, N. J.** — Founded in 1866 under the auspices of the Methodist Episcopal Church as an institution to train men for the service of the church. Graduates of reputable colleges are admitted without examination; other applicants must pass the examination. Greek is required from all. The three-year course leads to the degree of Bachelor of Divinity in the case of those who are already college graduates.

**DREXEL INSTITUTE.** — An educational institution opened in Philadelphia in 1892. It owes its origin to an endowment of \$2,000,000 and a plant costing \$1,000,000 given by Anthony J. Drexel. The aim of the institute is to offer a training to young men and women preparing for industrial and commercial life. The chief emphasis is laid upon the applied sciences, but instruction is not limited to this alone and includes a broader intellectual culture. There are six departments, giving courses in the following subjects, — architecture, science and technology, commerce and finance, domestic science and arts, physical training. No degrees are conferred by the institute. Evening classes are held and free public lectures and concerts are given. The library contains some 40,000 books, dealing mainly with the arts, sciences, and technology. The museum includes valuable collections of the ceramic arts, bronzes, ivory carvings, textiles, embroideries, and furniture. About 2500 students annually avail themselves of the courses offered by the institute.

**DRILL.** — The systematic endeavor to fix firmly habits or associations between stimuli and responses. These associations may connect sense stimuli with ideas or with movements, or ideas with other ideas or with movements. We may drill to establish physical or mental habits, to strike a nail properly with a hammer or to fix a name in memory. The effectiveness of drill may be said to depend upon three factors, repetition, intensity, and satisfaction. Repetition is so important and so universal a factor in drill that it is commonly regarded as constituting its meaning. To drill, it is often thought, is to go over again and again. However, as a phase of teaching, it is

better to define drill from the point of view of its function, which is that of fixing associations, rather than from that of any special method of accomplishing this function, however universal it may be. The effectiveness of repetition is enormously enhanced by intensity in stimuli or responses or both. One of the most important methods of getting this intensity is by concentrating the attention. One establishes an association far more rapidly by attending carefully to what he is doing when he repeats it, than when he merely goes through this process mechanically. Again, it is evident that when the results of association are persistently unpleasant, repetition, so far from strengthening habits, tends to discourage them and to break them up. Monotonous repetition may be of little effect, but disagreeable drill may create a repugnance to the processes involved that may actually unsettle the associations. It follows that the school cannot afford to let drill be merely mechanical, or to render it markedly unpleasant.

Drill produces its most pronounced effects in its early stages. This fact has been especially emphasized by Ebbinghaus in his experiments on memory described in the monograph in *Über das Gedächtniss*. Bair in his discussion of the Practice Curve (Mon. Supplement, *Psych. Rev.*, No. 19) has brought out the same fact in regard to motor habits. Ebbinghaus tried to establish the definite mathematical law that the effect of subsequent repetitions diminishes constantly in geometrical progression. So far as experiments show it seems as though there is a limit beyond which further repetition produces no effect. However, Bryan and Harter in their "Studies on the Telegraphic Language" (*Psych. Rev.*, Vol. VI), demonstrated that after this limit seemed to have been reached, and progress had for some time been at a standstill, a new period of advance in skill might appear. We have here the celebrated plateau theory. No established explanation of the plateaus exists, but they are generally supposed to be periods of fixation and organization, that show no immediate result in the accuracy or rapidity of the habit, but are really a preparation for more complicated habits by which a number of stimuli are correlated and the proper complex response initiated through what is practically a single act of attention.

Practical experience with the poor results of mechanical drill has led it to be discredited and very largely abandoned by the modern school. It has been laid down as a principle that drill should never precede an intelligent comprehension of the habit of thought or action to be taught. Thus the early stages of drill are made to involve concentrated thought and interest, and so to be especially effective. When, however, this initial step in learning is not followed by further drill, it is evident that it is likely that the habit involved will prove unreliable. All teachers recognize this, but they differ in regard

to the method by which the drill should be given. We may distinguish between those who believe only in incidental drill, and those who would make it fairly systematic. Incidental drill we may define as such practice in the habits that have been taught as comes with their inevitable use in the later work of the school and of life. On the other hand, systematic drill is that which is definitely planned with the idea of establishing the habit. Systematic drill may take the form of mechanical repetition or it may mean a review of the habits in different concrete applications. The latter method combines the advantages of persistent practice with those of concentration and interest. It is thus the most effective kind of drill. It is, however, not easy to insure that whatever the school wishes to teach can be made the subject of such treatment. It follows that as yet the teachers have not found it possible to dispense with systematic mechanical drill, although its disappearance may be regarded as an ideal toward which the school should strive. It is interesting to note that the *Springfield Tests* (*q.v.*) revealed that in the old-fashioned school, where mechanical drill was more in vogue, children did not learn to spell, to write, to solve arithmetic problems or to give the locations of geographical places any better, or even so well as they do to-day when incidental drill is so largely relied upon. **DRINGENBERG, LUDWIG.** — A schoolmaster of the fifteenth century. Born about 1430 in a town in Westphalia from which he took his name, he was sent to the school at Deventer which then stood under the wholesome influences of the Brethren of the Common Life (*q.v.*). After studying at Heidelberg he was called to take charge of the Latin school at Schlettstadt, a flourishing Alsatian town, in 1450. At this school his influence was directed to breaking down the old scholastic traditions and to introducing the culture and piety of the Brethren of the Common Life. In place of the old lifeless study of grammar he introduced the reading of the Latin classics. His services were of importance in helping to bridge over the period between the scholastic and humanistic influences in the schools. Schlettstadt itself became under the influence of Dringenberg and his pupils and successors one of the centers of the humanistic movement. He died in 1490.

**DRINKING FOUNTAINS.** —

Where pure water under pressure is furnished to school-houses, there is no longer any excuse for drinking cups, and all the trouble, loathing, and possible contagion incident to common drinking vessels. Drinking fountains, when properly made, save time, prevent the careless use of water in or out of buildings, and best of all insure perfect cleanliness. The principle involved in the construction of all forms of drinking fountains consists in furnishing an opportunity for a child to drink from a

stream of water bubbling up directly from the supply pipe and at the same time insuring that the mouth of the drinker does not come in contact with any part of the fixtures or that the water not swallowed cannot fall back to pollute the rising stream of pure water. A fountain must also meet certain other requirements. The stream must be steady, must be large enough to supply sufficient water for ordinarily rapid drinking, must mount at least two inches above any part of the bubbling cup, must offer as little chance as possible for mischievous children to "squirt" each other, and must be as economical of water as legitimate demands will permit. The material of which they are made should be such that they can be easily kept clean and perfectly sanitary. A good quality of white well-glazed porcelain is perhaps the best material used. Metal or marble is hard to keep clean or free from rusts or stains. The nozzle of the service pipe should be nickled or in some better way rendered completely rustproof. All exposed parts should be strong, and provision should be made to prevent clogging of the catch basin, so that the unused water will disappear at once. Children take a peculiar delight in dabbling in water, and this universal and almost resistless craving will assert itself and cause trouble unless the construction of the fountain is such as to make this practically impossible. The cuts here reproduced represent two forms of fountains which, when properly set, are thoroughly sanitary. Doubtless there are others equally perfect.

Single fountains can be distributed throughout a school building as demands dictate; but as far as possible they should not obstruct the halls, and yet should be visible from the halls. Special alcoves or niches should be arranged for them. In addition to those on the main floors, there should be "batteries" of them in the basement or in some inclosed place near the playground. There is always a rush for a drink after play, and many pupils must be supplied quickly. The accompanying cut shows a provision to supply this demand. The exorbitant price which prevails for such appliances has prevented their almost universal use where pure running water is to be had. It is, however, entirely possible for any plumber to arrange a less expensive series of fountains for a playground or a basement. A series of short pieces of water pipes set at right angles to a main feed pipe about thirty inches apart and extending over a common waste water trough can be made into fairly satisfactory fountains at very little expense. One of the simplest methods of preparing these is to cover them with a close-fitting nickled covering close the outer end with a cap and drill a hole on the upper side a few inches from the cap. By the use of a valve which can be adjusted to suit the pressure, and one to turn the water on and off as needed, a series of jets can be made to bubble up so that almost perfect sanitary conditions may prevail. Care and a bit of experimenting will be necessary in order to adjust the size of the holes, and the valves to the pressure of the water. Of course this arrangement will not be so neat, neither will it be so completely satis-

factory as the one shown in the illustration, but many so made have proved quite satisfactory. Every modern school should be supplied with drinking fountains for the sake both of decency and safety. F. B. D.

**DRISLER, HENRY** (1818-1897). — Head of the department of Greek in Columbia University for many years, and the editor of Harper's classical series and several Greek lexicons, was graduated at Columbia in 1839. For four years he was instructor in the gram-

mar school connected with Columbia, and from 1843 to 1894 he was professor of Greek and Latin at Columbia. W. S. M.

**DROPSIE COLLEGE, PHILADELPHIA, PA.**—An institution opened in 1909 as the result of a legacy left by Moses A. Dropsie for the promotion of and instruction in the Hebrew and cognate languages and their respective literatures and in the Rabbinical learning and literature. Candidates who have received the degree of Bachelor of Arts from a college or university of good standing are admitted to the courses leading to the degree of Doctor of Philosophy. There is a faculty of five members.

**DRUGGIST, EDUCATION OF.** — See PHARMACEUTICAL EDUCATION

**DRUIDS, SCHOOLS OF THE.** — Little is known of these institutions and all the evidence on the subject rests on a statement found in Cæsar, *Gallie War*, Vol. VI, pp. 13, 14. In describing the Druids Cæsar says, "a great number of youths resort to them for instruction." The curriculum consisted in memorizing a large number of verses, and "they also discuss and teach the students about the stars and their movement, about the size of the universe, about natural phenomena, and the power and authority of the gods." Instruction was purely oral, although writing was known and used. The course, which lasted twenty years, seems to have been a period of apprenticeship for the attainment of the druidical position. Cæsar points out that exemption from military service, taxation, and other burdens make the position so attractive. Still following the same authority, the schools flourished in Britain and were visited by students from Gaul. Of the numerous verses to which Cæsar refers three survive in the writings of Diogenes Laertius, Proemium, five, "Revere the gods, — do no evil, — practice bravery."

Cæsar's observations on folkways and customs of the people with whom he came in contact are usually so sound, that there is every reason to believe his account of the schools of the Druids, with this reservation, however, that he is the only authority.

**DRURY COLLEGE, SPRINGFIELD, MO.** — A nonsectarian, coeducational institution, organized in 1873. The institution labored under great financial difficulties until 1892, when a movement was inaugurated to place it upon a sound financial basis. A gift of \$50,000

from Dr. D. R. Pearsons of Chicago, one of an equal amount from the General Education Board, and a third gift of the same size from Mr. Andrew Carnegie, enabled the endowment to be greatly enlarged, new buildings to be added to the equipment and the curriculum to be strengthened. The Congregational College and Education Society has always lent its support to Drury College. The board is a self-perpetuating body of 21 members, including the president *ex officio*; one group of five trustees is elected each year to serve five years. In 1908 Drury College was accepted by the Carnegie Foundation for the Advancement of Teaching (*q.v.*). The institution maintains a college of arts, admission to which is by examination or certificate from an approved high school; a conservatory of music; an art department; a military department, an academy, and a night school. Grounds, buildings, and equipment are valued (1909) at \$141,232.89. The total productive endowment is \$240,000; the total annual income is \$30,701.88. There is an outstanding debt of \$43,549.57. The average salary of a professor is \$2100. There are twenty-five members on the instructing staff. The student enrollment in 1910-1911 numbered 450. C. G.

**DUALISM.** — Philosophic systems which make a hard and fast antithesis between terms which are related to each other in experience are known as dualisms. The philosophic dualisms that have chiefly influenced education are those between spirit and matter, mind and body, logic and psychology. The first has shown itself in the tendency to set humanistic studies dealing with mental products, over against the naturalistic dealing with physical nature. The dualism between mind and body has manifested its influence at some periods in contempt for physical health and training, and in ascetic aspects characterizing scholarship; and at other times in complete separation of methods of physical and mental culture and in contempt for all subjects in education that involved manual activity. The dualism of logic and psychology has reflected itself in treating subject matter and method as independent divisions of education, subject matter being arranged on strictly logical principles, while method is supposed to deal merely with psychological devices by which the approach of individuals to this ready-made subject matter may be facilitated. For educational purposes, the opposite of dualism is not necessarily monism, but a philosophy which regards the distinction of antithetical terms (like those just mentioned) as relative and working, not fixed and absolute, so that they are capable of coming together in functional unity. J. D.

**DUBLIN UNIVERSITY, TRINITY COLLEGE, DUBLIN.** — The oldest institution giving university education in Ireland.

Attempts to found a university were made as early as 1311, when a Papal Bull, sanctioning the project, was issued. The scheme, however, though twice revived at that period, fell through. The project was again renewed about 1550, but without success. In 1590 a petition was made to the Mayor and Corporation to found an institution to provide a higher education for the natives in order to prevent the constant drain to foreign universities. In view of its subsequent history, it is interesting to note that in its beginnings, the Dublin University received the support of Protestants and Catholics alike, as also of English residents and natives. In 1593 Trinity College was opened. James I gave his patronage as well as some property, and the privilege of sending two members to Parliament. Through the provost and the other members of the faculty an intimate connection was maintained with Oxford and Cambridge. A result of this was an attempt to realize the English conception of a university as a collection of colleges. The attempt was, however, unsuccessful. No religious tests were at first imposed, but a change of policy was introduced when Archbishop Laud became Chancellor, and since that time, with brief intermissions, the university has remained a stronghold of the Established Church, although degrees are given since 1794 without religious tests. The university suffered largely through the unsettled state of Ireland and material progress was not assured until the eighteenth century. The early curriculum included classics, theology, philosophy, and mathematics. In the last field Dublin University early established a great reputation. But the most rapid development took place in the last century. Degrees in classics (1816), mental and moral science (1834), theology (1833), natural science (1831), law, and history (1856), were established in many cases before they existed at Oxford or Cambridge. A medical school had been in existence since the seventeenth century. In 1842 a chair in civil engineering was established and the degree in that subject was introduced in 1872. For the professional schools the entrance requirements are a degree in arts. In addition to the granting of degrees to residents of Trinity College, degrees are also given to nonresidents on passing the necessary examinations, — a practice which contributed largely to the promotion of higher education in Ireland. With Dublin University is affiliated Magee College, Londonderry. All classes, examinations, and degrees in arts, medicine and law are open to women. Formerly Dublin degrees were granted to women who held certificates from Oxford or Cambridge, but this practice has recently been abolished. Trinity College possesses a remarkable library which ranks as one of the most important in the world. Its history is noteworthy as having been twice aided by subscriptions from the English army engaged in Ireland in 1601 and

1661. Among the valuable collections are Biblical and Oriental Mss., *editions principes*, including Petrarch's *Sonnets* (1470) and Dante's *Divine Comedy* (1472), and a large number of Irish illuminated books dating back to the eighth and ninth centuries, including some of the masterpieces of the early art of illumination and copying. Of a large number it is only necessary to mention the *Book of Kells*, "the most beautiful book in the world." In English and Irish history the alumni of Trinity College, including Burke, Swift, and Moore, have played an important part in all walks of life.

**DU CANGE, CHARLES DU FRESNE, SIEUR.** — Born at Amiens in 1610, died in 1688. He was educated at the Jesuit college in Amiens, studied law at Orleans and afterwards practiced in Paris. Du Cange was profoundly devoted to the study of medieval history, and the great monument to his name is his three-volume glossary of medieval Latin, and his two-volume glossary of medieval Greek. The former work appeared in 1678, the latter in the year of his death. Du Cange wrote also on language, history, geography, heraldry, law, numismatics, epigraphy, and Greek and Latin paleography. He discussed in detail jousts, the round table, the quintain, coats of arms, the origin of the colors and metals employed in heraldry, and the coinage of the Emperors of Constantinople. His greatest historical work was done in the field of Byzantine history. Du Cange was a type of the best seventeenth century school of thoroughly scientific workers in the field of literature and history.

**DUELING IN THE UNIVERSITIES.** —

The code of honor which prescribes dueling as the only mode of atoning for an insult has been retained in the German universities as a survival of the Middle Ages. The duel or *Mensur* is encouraged by the various student associations, although there has been a tendency recently for the formation of nondueling associations. The universities officially set their faces against the practice and the scene of the encounters is usually outside the jurisdiction of the authorities. The causes for this form of reparation are frequently very slight and trifling, often giving the impression that the so-called insult

is nothing more than a pretext to secure a duel. The *Mensur* in most cases is fought with the *Schläger*, a long, whiplike sword with a basket hilt. The aim is to draw blood or to extend the contest over fifteen minutes. The eyes, neck, chest, and right arm are all fully protected; the eyes with a steel spectacle frame, and the neck with a padded leather jerkin. A medical man is always in attendance. In some forms of dueling the seconds stand by their principals to ward off foul or dangerous blows. Saber and pistol duels are also known, but are rare. There is some danger that the practice of dueling may, in many cases, lead to bullying on the part of the skilled swordsman, and such cases are not unknown. On the other hand, the *Mensur* calls for a certain kind of courage, a quick eye, a ready command of the wrist and body; while, as Paulsen remarks, "the rapier puts all upon an equal footing." In addition to the duel as a form of securing satisfaction for an insult, there is the *Bestimmungsmensur* (regular match or bout) among members of the various societies, in which a little of the acrimony of the duel is absent. But whether any form of sport which goes to the extent of bloodletting, and, as frequently happens in the case of the *Mensur*, permanent disfigurement should be encouraged, it is difficult to say. The students of each nation have their own traditions, and their old-established forms of sport, and it is not an easy matter to suggest that the German student ought to play football, or the American ought to reform his particular sports. The opposition to dueling is increasing in Germany, but to the popular mind the typical German student is still the man with a scar. There is no doubt that the introduction of athletics, under royal patronage, will to a large extent leave dueling in the hands of the few bolder but more reckless spirits.

See STUDENT LIFE.

**DUER, WILLIAM ALEXANDER** (1780-1858).—Jurist and educator; was the fifth president of Columbia College (1829-1842). He was one of the promoters of the American Lyceum Association (*q.v.*), and for several terms its president. W. S. M.

**DUGARD, WILLIAM** (1606-1662).—English schoolmaster, educated at the Royal Grammar School, Worcester, and entered Sidney Sussex College, Cambridge, 1622. Dugard took his B.A. in 1626, and became usher of Oundle School, and in 1630 was promoted to the headmastership of Stamford School. In 1637 he became headmaster of

Colchester grammar school, where he raised the numbers from nine to sixty-nine. In 1642-1643 he resigned, after a quarrel. In 1644 he succeeded to the chief mastership of Merchant Taylors' School, London. In 1648 he was made Examiner of the Company's schools in the country, with a fee of £20. Soon after he set up a private printing press, and busied himself in politics. It seems that Dugard was one of the printers who took part in the publication of the famous *Εἰκὼν Βασιλική*. In 1650 Dugard was committed, by order of the Council, to Newgate Prison, for printing pamphlets against the Parliament. He was set at liberty, it is said, by the interposition of John Milton, but a new headmaster of Merchant Taylors' School had been appointed, and Dugard opened a private school. He made his peace with the state, and printed Milton's answer to Salmasius. Within five months from release from prison, Dugard was reinstated in the headmastership of Merchant Taylors' School. His boundless energy again led him into trouble. In 1658 he printed the *Racovian Catechism*. The copies were taken and publicly burnt. In 1660 he was dismissed on the ground that by statute only 250 boys were to be admitted to the school, and he had increased the numbers beyond the limit, and acted irregularly in certain proportions of free and paying boys. In July, 1661, Dugard again opened a private school, and soon had 193 pupils. He died in 1662.

Dugard was the leading Puritan schoolmaster. He wrote school textbooks of some merit. In regard to Dugard's *Elementa Rhetorices* (3d ed., 1665) and his *Rudimenta Græcæ Linguae* (c. 1656), Charles Hoole (*New Discovery of Old Art of Teaching School*, 1660) speaks in commendation, and mentions his *Lexicon Testamenti Alphabeticum*. Dugard also produced editions of Lucian and the Greek Manual of Seidelius for school use. Of his books, however, none is now so interesting as his translation in 1656 of Comenius's *Janua Linguarum*, decidedly the best of the English versions of Comenius's *Janua*. F. W.

**DUISBURG, THE UNIVERSITY OF, RHINE PROVINCE, PRUSSIA**.—Established under the auspices of the Reformed Church in 1655. It never attained any prominence, and, like a number of other German universities, came to an end (1818) during the period of reconstruction after the war of liberation.

**DULWICH COLLEGE, LONDON**.—See COLLEGE; COLLEGES, ENGLISH; GRAMMAR SCHOOLS; PUBLIC SCHOOLS.

**DUNCE**.—A term commonly used of a pupil of poor abilities who is dull and slow at his books. The word, however, has very interesting antecedents which link it with the scholastic move-

ment. The many followers of Duns Scotus (*q.v.*) early acquired the reputation for quibbling, hairsplitting, and sophistries. By their contemporaries they were called indifferently Scotists or Dunses. Their opposition to the humanistic movement helped to give the term a new connotation, and a Duns or Dunse came to mean a dull person, a blockhead, an unscholarly person who could not recognize the value of the new learning. The term was already in use in this sense at the end of the sixteenth century, and is thus explained by Cotgrave (*q.v.*). The transference of the word to the schoolroom was a very simple matter. With the use of the term came the dunce's cap of conical shape and variously ornamented with a capital D or donkey's ears. A new pedagogy based on an improved psychology is gradually driving this appellation, with many others, out of the school.

The term "duns" or "dunce" was also used to refer to copies of Duns Scotus and to any similar kind of text in theology or logic. Compare the use of the term *donat*, where the personal name came to be employed for the man's work. See Murray's *Oxford Dictionary*, *s.v.* "Dunce."

See REWARDS AND PUNISHMENTS.

#### DUNDEE, UNIVERSITY COLLEGE OF.

-- A coeducational institution, since 1897 a constituent college of the University of St. Andrews (*q.v.*); was founded and endowed in 1881 by Miss Mary Ann Baxter of Balmavie and John Boyd Baxter, LL.D., Dundee, who conjointly donated £50,000 for the purchase and equipping of buildings, and £100,000 as a permanent endowment fund for the provision of teaching. The college was formally opened in 1883 under the principalship of William Peterson. The deed of endowment directs that the college shall be for the promoting of the education of persons of both sexes, and for the study of science, literature, and the fine arts; and it is further stipulated that "no student, teacher, or other person shall be required to make declaration as to religious beliefs, and nothing shall be introduced in the manner or mode of instruction in reference to any religious or theological subject which can reasonably be considered offensive to the conscience." As a consequence of this condition, the work of the college has been confined to the teaching of arts, science, medicine, and law. At the present time, courses of study are provided leading to graduation in arts, science, and medicine. In addition to these courses, evening classes are conducted, intended for those who, while unable to enter on a regular course of training during the day, are yet desirous of gaining a systematic knowledge of the subjects they elect to study.

A. D.

**DUNS SCOTUS, JOHN.** -- "The Subtle Doctor." One of the half dozen most cele-

brated scholastic teachers; "the acutest and deepest thinker of the Christian Middle Ages," says Windelband; theologian, philosopher, author, and founder of the school of Scotists; not to be confused with the founder of scholasticism, Scotus Eriugena (*q.v.*). The authorities are not agreed as to his birthplace or the main dates in his life, except that he died young in Cologne, Nov. 8, 1308. He was born probably between 1265 and 1275, either in Dun, Ireland, or in Duns, Scotland, or in Dunston, England. All have claimed him; the Irish have spread his fame most. He came of noble blood; at an early age became a Franciscan friar; studied, especially mathematics, at Merton College, Oxford, learning more from books than from his teacher; became *Magister* of all the sciences when still young; in 1301 was made professor of theology in Oxford; attracted throngs of students as a lecturer; wrote on the works of Aristotle (*q.v.*) and on the *Sentences* of Peter Lombard (*q.v.*), his comments on the first part of the *Sentences* receiving particular praise from later theologians; in 1304 went to Paris as professor of theology, becoming thus twice a doctor; taught here with great distinction, winning his title of "the Subtle Doctor" through his triumphant defense, against two hundred objections, of the Immaculate Conception of the Blessed Virgin; continued his writing; was made regent of the theological school; in 1308 was sent by the Franciscan general to Cologne to engage in a controversy with the Beghards and to assist in founding a university; was received there by the nobles and magistrates with greatest ceremony, but was taken off shortly afterward by apoplexy.

Duns Scotus made at least three important contributions to the thought of his time: first, he separated philosophy and theology; second, he made theology rather ecclesiastical than biblical in character; third, he made philosophy voluntaristic rather than intellectualistic in character. He separated philosophy and theology by making the one earthly, the other heavenly; the one interested in proofs, the other in doctrines; the one intellectual, the other practical, -- the two were so divorced that what was philosophically true might be theologically false. The authority of Scripture depends on the authority of the Church; thus he could defend the Immaculate Conception of the Virgin, and thus his theology was ecclesiastical. As to his voluntarism, he holds that the individual alone truly exists; that the human will is free; that it is not bound by the reason; that it is free to choose or not; that it is free to choose between two possibilities; that attention increases the distinctness and intensity of ideas given in the course of nature; that we can will to think; that not even the will of God is bound by His wisdom; that the Creation might have been different; that God does not choose a thing because it is good, but

it is good because He chooses it; that by commanding murder God could make it no crime; that man coöperates with God in his own salvation, Christ being the door through which man himself must walk. On all these, and many other similar matters, he and his Franciscan followers, the Scotists, were opposed by St. Thomas Aquinas (*q.v.*), and his Dominican followers, the Thomists, and on account of these views he was not canonized by the Roman Catholic Church. As Erdmann says, "In spite of the fact, therefore, that Duns is the truest son of the Romish church, he has brought scholastic philosophy to a point where it is obliged to announce to Rome the termination of its period of service." Unfortunately Scotus is still without an exhaustive monograph.

**DURATION**.—That phase of experience whereby the subject recognizes the succession of experiences. When we are conscious of such a succession, that is, of a transition in time, we have an experience of duration. The process by which we recognize duration has been much discussed in psychological literature. To one group of writers, such as James, duration seems to be a fundamental characteristic of all experience. James puts duration on a par with the intensity and quality as an essential characteristic of all mental experiences. Other writers make an effort to explain the recognition of duration as dependent upon the comparisons which arise through fluctuations in experience. Thus when the transition is made from a given tone to a second tone, there is not only a change in quality, but a shock of transition. This shock develops in a type of recognition which is related to comparison between the two tones. The special forms of perception of duration are of interest because they are intimately related to the contrasts which emphasize transition. Thus in English poetry the duration of a foot is largely affected by the degree of emphasis. A very intense expression may, in some cases, be of equal value with an unaccented expression of much longer duration. If a contrast is so great as to surprise the individual and attract his attention to the content of experience, the duration phase of the experience may be entirely lost sight of. Those psychological writers who do not agree with the position of James that duration is a fundamental characteristic of mental experience seek to explain the perception of duration through a study of contrasts and moments of transition. In some cases the sensations which accompany these experiences of transition have been treated as of great importance in determining the perception of duration.

**DURHAM, UNIVERSITY OF**.—An educational institution which is doing important

work in providing university studies in the northeast of England. The present foundation was established in 1831 by the Bishop, Dean, and Chapter of Durham Cathedral. Durham County had, however, through its cathedral and monastic foundations, had an intimate connection with the provision of university education in the fourteenth and fifteenth centuries, since they maintained a cell at Oxford for monks of Durham, to pursue university studies. This early foundation at Oxford was, for a time, known as Durham College. It came to an end in 1540, when the property was confiscated, and in 1555-1556 Trinity College was built on its site. Henry VIII planned a college at Durham, but nothing was done until 1657, when Cromwell interested himself in the matter and granted the cathedral property for the purposes of a college, but although letters patent were given to this institution, it did not receive university powers. It was vacated at the Restoration. Nothing more was done until 1831, when the Bishop, Dean, and Chapter of Durham interested themselves in projecting an academical institution or college, or university. The charter for a University of Durham was received in 1837, and degrees were then for the first time conferred. Durham Castle was appropriated to the use of the university. The subjects of instruction were divinity, Greek and Latin, mathematics, and natural philosophy. The university remained under the dual control of the Dean and Chapter on the one side, and the Warden and Senate on the other, although attempts have been made, unsuccessfully, to remove this anomaly. Women were admitted in 1895. The residence for an arts degree was reduced in 1865 from three to two years. The university was the first to offer a course in civil engineering, in 1837; but there did not seem to be a demand for this, and it was dropped. The theological course, which, at present, forms an important part of the work of the university, was established before that at Oxford or Cambridge. In 1870 the college of medicine at Newcastle-on-Tyne became a constituent part of the university, which was empowered to grant recognized degrees in medicine. In 1871 the college of science, now Armstrong College, also at Newcastle, was brought into close connection with the university, which allowed a large part of the work of the college to count toward degrees and diplomas. The college of science, however, developed on its own lines, and now offers courses in the humanities and education. With Durham University are affiliated Codrington College, Barbados, since 1875, and Fourah Bay College, Sierra Leone, since 1876. In 1895 the university undertook the examination of secondary schools. University College and Bishop Hatfield's Hall are maintained as residence halls for men, and Abbey House as a hostel for women.

FOWLER, J. T. *Durham University*. (London, 1904).

**DURUY, VICTOR** (1811-1894). -- French historian and educator. He studied at the *École Normale Supérieure* (1830-1833), and subsequently was professor of history at the Lycée Henri IV for a quarter of a century, academy inspector, general inspector of public instruction, and finally professor of history at the *École Polytechnique*. He was Minister of Public Instruction under Napoleon III (1863-1869), and instituted important reforms in the system of public secondary education. In the boys' schools, the old narrow humanistic course partially gave place to a broader scientific training, with more emphasis upon history and modern languages. Public secondary education for girls is largely due to his initiative, for his recommendations were directly responsible for the establishment of the secondary courses for girls, which were subsequently evolved into the present lycées and collèges. He occupied a seat in the Senate (1869-1870), retiring to private life after the events of that year. He was author of *Histoire de France* (2 vols., 1852); *Histoire des Romains* (7 vols., 1879-1885); *Histoire des Grecs* (3 vols., 1886-1891); as well as of several school histories.

**Reference:—**

LAVISSE, *Un Ministre Victor Duruy*. (Paris, 1895.)

**DURY, JOHN** (1596-1680). -- Protestant divine who devoted his life to an attempt to secure unity among the Protestants of Europe. Among his numerous writings are several of educational interest. In a *Motion tending to the Public Good* he dealt with schemes of education. In an *Exercitatio of Schooling*, which is extant in manuscript only (Sloane Mss., British Museum 649), he advocated a scheme of public education for all classes of society -- schools common to all to give a knowledge of "things"; schools for the teaching of ancient languages as a preparation for the professions; schools for teaching of modern subjects as advocated in the academies (*q.v.*) of the time to prepare nobles and gentlemen for "public charges in peace and war." But his most important work is the *Reformed School*, which he probably wrote under the inspiration of his friend Hartlib (*q.v.*) in 1650. While this work contains no original matter, it is significant as a reaction of an educated man to the educational ideas of his time. In the *Reformed School* there are echoes from Bacon, Comenius, and Milton, with some contribution from the publicists of the day. Dury is the spokesman for a religious teaching association which Hartlib wished to form in England on the model of those in France. From the *Reformed School* something of the aims of the association is learned. Godliness, bodily health, manners, and "last and least part of true education, Proficiency in learning," are to be the ideals.

Dury is not behind contemporary writers in attacking the learning of words, and is a strong advocate of realism (*q.v.*); the "Tongues," he says, "without their subordination unto arts and sciences are worth nothing towards the advancement of our happiness." Sense, tradition, and reason are the three sources of knowledge, and everything must come through the senses. As there is a gradation of the sources of knowledge, so there is a hierarchy of faculties. Dury strongly advocates that consideration should be paid to the "natural capacities" of children, and that teachers should assume part of the toilsomeness of their business in order to relieve the children. Formal schooling is not to begin until eight or nine years of age, although Dury suggests a "Nursery" which corresponds to the "School of Infancy" of Comenius. In *A Supplement to the Reformed School*, there is an excellent presentation of the relations to each other and the respective functions of the school and college, and of the qualifications of students and professors, "none should be admitted into any Colleges but such as will join with others, to elaborate some Profitable Tasks, for the Advancement and facilitating of superstructure in things already by some discovered, but not made common unto all: And that none should be made Publick Professors in Universities, but such as have not onely a Publick aim, but some approved Abilities, to supply some defects and to Elaborate some desiderata of usefull knowledge, or to direct such as are studious. . . ."

He was for four years principal of the Hopkins Grammar School, six years a tutor at Yale, and several years principal of the academy at Greenfield, Conn. He was president of Yale from 1795 to 1817. Author of several books on religion and travel. He died at New Haven Jan. 11, 1817. W. S. M.

See YALE UNIVERSITY.

**DYNAMIC.**—Relating to force or energy in active operation. The term was first used technically in physics to denote the doctrine of force causing motion, as distinct from static, referring to matter in a condition of rest. The distinctions were applied to sociology by Comte, "static" to designate the structure of society, "dynamic," the laws of social change. In psychology, "dynamic" has been used as an equivalent of functional psychology (*q.v.*) as distinct from the analytic—or structural—psychology of elements. In educational literature, the term is commonly used to denote emphasis upon the active and motor processes, in distinction from attitudes of passivity and receptivity and docile absorption. J. D.

See ACTIVITY.

**DYNAMOGENIC METHOD.**—In his volume on *Mental Development in the Child and Race*, Professor Baldwin describes a number of experiments in which he studied the perceptual processes in young children by allowing them to reach for objects which they preferred. Thus he attempted to discover which colors children recognize and prefer by offering them a variety

of colored objects and counting the number of times they reached for the one or for the other color. In view of the fact that this method employs activities or expressions for the purpose of studying the mental processes of the individual, the emphasis is laid upon the dynamic phase of the process; hence the name employed in describing the method. The same type of method has been described by other experimenters in psychology as the expression method. This is contrasted with the various impressions of psychological experimentation.

See EXPRESSION METHODS.

**EACHARD, JOHN** (1636?-1697). — An English divine, master of Catharine Hall, Cambridge, from 1675, and Vice-Chancellor of the University in 1679 and 1695. He showed great energy in securing donations for the rebuilding of his college. In his own time he had a great reputation as a wit and satirist, to which Swift bears testimony. From the standpoint of education his most important work is *The Grounds and Occasions of the Contempt of the Clergy and Religion enquired into. In a Letter to R. L.* (London, 1670), in which he subjects the education in the schools of his day to a scathing criticism. He asks, for example, "Whether it be unavoidably necessary to keep lads to sixteen and seventeen years of age in pure slavery to a few Latin or Greek words? . . . Suppose some part of the time were allotted them for the reading of some innocent English authors." He recommends the study of arithmetic, geometry, "and such alluring parts of learning." He objects to the sugar-coating of lessons by devices such as those recommended by Comenius, to whom he refers; the fine pictures and games "by no means is such a lasting temptation as the propounding of that which in itself is pleasant and alluring." He points out what poor material is sent to the universities, not only badly prepared intellectually, but also financially, to learn "a little logic, a little ethics and, God knows, a very little of everything." He proposed that English exercises should be imposed upon lads in the schools, since English and not Latin is the language spoken generally. From this point Eachard goes on to indicate the defects of the clergy, especially in rural parishes, due to bad preparation and poverty. This essay was used by Macaulay in his *History of England* in the account of the clergy of the Restoration period.

**EAR.** — The ear is one of the highest organs of sense. It is protected by the hardest bone in the body, namely the petrous bone.

is carried to the sensory cells which are imbedded deep in the bone, by a complex mechanism of transmitting and receiving organs. In addition to sensory cells which receive sound stimulation, the ear also contains a system of canals known as the semicircular canals which constitute an organ of equilibration. This organ of equilibration has no connection in its present highly evolved form with the function of hearing, though in the lowest animal forms hearing and equilibration are phases of a simple function, including all sensitivity to motion either of the external medium in which the animal lives or internal motion of the body. The major parts of the ear are the outer ear, consisting of the cartilaginous pinna, or visible ear, and the external meatus, or passage through which the sound is carried into the inner recess of the organ. Second, there is a middle ear separated from the outer ear by the tympanic membrane and connected with the outer world by the eustachian tube which passes from the middle ear to the throat cavity. Finally, there is an inner ear which is filled with liquid and includes a complex membrane known as the basilar membrane, upon which the sensory cells are seated. The structure of the inner ear and its relation to sound vibrations is such that each different pitch affects a separate group of cells. For this reason complicated sound vibrations may be analyzed by the ear into their component elements. Complex sounds are thus recognized in sensation in a very different way from complex colors, for the sensory surface of the eye does not analyze its impressions. The ear is also distinguished from the other organs of sense by the fact that it does not have any vivid after-effects from stimulation. There are practically no auditory after-images. For further discussion of the ear see NERVOUS SYSTEM.

C. H. J.

**Ear, Hygiene of.** — Among normal individuals there seem to be great individual variations in range of hearing, especially as regards the upper tone limits. While it is ordinarily supposed that the human ear can hear tones caused by vibrations within the limits of sixteen to twenty a second and 30,000 to 32,000 per second, recent investigations of the hearing of school children by Reik in Baltimore indicate that for many individuals the limits are much greater, and that for young people the normal limit for high tones is far above 32,000, and in many reaches 70,000 or more. So great are the individual variations that no definite norms can be established. Also individual differences are found in general auditory acuity, and the keenness of the sense of hearing probably varies with changing conditions of nutrition, fatigue, climate, etc. Just what is the range of normal variation is not known; but children who cannot hear what the majority of children can hear at a given distance are usually classed as deficient in hearing, and those that cannot hear at one third the distance that

others can hear are deemed distinctly defective. (See TESTS OF HEARING.)

Diseases of the ear are common among children. The deafness that is apt to result is a defect that especially concerns school hygiene. The results of investigations vary greatly; but tests of hearing in thousands of schools have shown that from ten to thirty per cent of all school children are likely to have some defect of hearing in one or both ears. This is a serious handicap in school work. Children partially deaf may hear for a time in a dictation lesson or the like, then fail to hear, and thus misunderstand, and are blamed by their teachers for dullness or perverseness; and, even when such children hear, the strain upon attention in listening may be a serious matter. A knowledge of the condition of a pupil's hearing is important for the teacher; and for the sake of pedagogy as well as for hygiene, annual tests of hearing are desirable.

Bezold and many others have found indications of a correlation between the hearing of school children and their mental ability as shown in school work, a much larger number of dull children and laggards being found among those with defective hearing. Dr. Bruner, it is true, found no very considerable evidence of a correlation between acuity of hearing and intelligence. Nor are the results summarized by Ayres very striking in this respect, although he did find a larger percentage of children with defective hearing among the retarded than among the normal. Dr. Kerr of London has made special investigations in regard to this point, and in his results a strong tendency appears for children whose mental condition is "excellent," to drop back into the ranks of the "good" or "fair" when handicapped by defective hearing. The investigations in concrete cases show that children with defective hearing are apt to be badly handicapped and mistreated by teachers who are unaware of the fact.

Among the causes of defects of hearing the following have been distinguished: adenoid growths, the various contagious diseases, especially measles, scarlet fever, and diphtheria, also serofula, colds, pulling of the ear muscles, careless methods of removing objects from the ear, violent sounds of cannon or the like, and carelessness in the hygiene of the nose. The most frequent causes are infectious diseases and diseases of the nose. The former cause deafness probably because in these diseases microorganisms develop in great numbers on the mucous membrane of the nose and are easily carried by the Eustachian tubes to the middle ear.

Some cases of psychic deafness are found, and a certain degree of psychic deafness is not uncommon. The facts are interesting and instructive to the hygienist. In hearing, as in other forms of sense perception, there are two factors, one subjective, one objective. Both

are necessary. The sound to be perceived must be aroused in the mind as well as strike the ear from without. In technical terms, there must be preperception as well as the external stimulus. Deafness may result from loss or serious defect in either factor. Thus it comes to pass that we find two kinds of deafness, namely, physical deafness and psychic deafness.

Total or partial deafness from lack of preperception is more common than one would naturally suppose. The children of deaf and dumb parents, whether their ears are defective or not, are liable to be deaf, unless they are sent away from home or receive special instruction, because the psychic factor is not likely to be developed. Proper habits of preperception are not acquired unless children have the stimuli from the conversation of their companions. In children who are partially deaf, where the defect occurred in early childhood, so that conversation was imperfectly heard, the defective hearing is likely to be in large part due to psychic defect.

Since deafness may result from defect either in the mental factor or in the physical organ, so also improvement may begin with either factor. Remarkable results may be produced by training in cases of psychic deafness. Cases have been reported where children apparently totally deaf have been taught to hear. Also where there is a partial defect of hearing the need of acoustic training is especially great.

A number of important points which bear upon the hygiene of the ear may be briefly enumerated. In the first place, primitive people apparently have no better hearing than civilized people, in spite of ordinary popular opinion. Dr. Meyers, in his study of the natives in the Torres Straits, found that there was no evidence of greater acuity of hearing, the difference between these natives and Europeans being apparently merely that they take an interest in sounds that the European does not give attention to. Dr. Bruner, also, in his tests made at the World's Fair in Chicago, found that both in keenness and range of hearing the whites surpass primitive peoples. Again the range of hearing for children is greater than for those in old age, quite apart from defects in the hearing. Ear disease is especially liable to occur in childhood. Children of the poorer classes, as found by investigations of the school physician in Leipzig, show many more defective ears than the children of the well-to-do, many ear diseases perhaps being the result of serofula, which attacks especially weaker and neglected children. The percentage of defective ears seems to vary also with the climate, a dry climate being favorable.

The ordinary rules of common sense should be regarded. Children should be trained not to put things into the ears, to be careful in case of any ear trouble not to let water run into the ears in washing and bathing, to avoid blowing the nose violently, and not to make loud noises

in the ears of their companions, and in case of earache to report the fact to parents or teacher.

The duties of the teacher in the hygiene of the ear are briefly the following: to ascertain what pupils have ear disease or defects of hearing; to place such in favorable seats in the school-room; to learn whether such children actually hear what is said to them; to report cases of apparent ear disease to parents, nurses, or school physicians, and in general to be hygienically watchful and sympathetic toward such children.

It is not the place here to treat the various diseases of the ear, but it may be noted that the most dangerous of ear diseases, namely, septic inflammation of the middle ear, Denker found in nearly two per cent of the 4716 German school children studied by him, *i.e.*, perhaps one for every school class. Children with this disease should if possible be taught in special classes, as a single case pollutes the air of the schoolroom and is liable to be a source of infection.

Among the results of the studies of hearing in school children the following should be emphasized: —

- (1) Apparently some thirty per cent of all school children have defective hearing.
- (2) Much can be done for such cases by proper medical and hygienic treatment.
- (3) Pupils partially deaf should receive psychic training.
- (4) Tests of hearing of school children should be made at least once a year, and all suspicious cases should be recommended to specialists.
- (5) There is considerable evidence of a correlation between the possession of normal acuity of hearing and good ability in class work.
- (6) Schoolhouses should be located in a quiet neighborhood, and the law should prohibit unnecessary noises in the vicinity.

W. H. B.

See NOSE, HYGIENE OF THE.

**Tests of Hearing.**—For educational purposes, the more elaborate tests of hearing, such as binaural pitch difference, integrity of the tonal scale, bone *vs.* air conduction, and the various tests which diagnose the seat of auditory defect are but seldom employed. The more common tests for auditory acuity may be divided, in terms of stimulus employed, into speech tests and instrumental tests, and in terms of procedure employed, into those that use the method of extreme range and those that use the method of percentage of accuracy at a constant range.

The *method of extreme range*, well illustrated in the ordinary watch test, consists in gradually moving the source of sound (or directing the pupil to move) from a position at which the sound is clearly heard to a position at which it can no longer be heard. Strictly, the reverse procedure should then be followed: that is, the distance from stimulus to ear should be taken such that the sound can certainly not be heard, and this distance should then be gradu-

ally reduced until the sound is heard. The average of these two determinations is the hearing distance. Although this method has been extensively employed in schoolroom tests, it entails one source of error that may be serious, *viz.*, the error due to reflection of sound from walls and objects; thus, a sound perceptible at thirty feet may be imperceptible at twenty-five feet. It is quite probable that many schoolroom tests are invalidated by this unsuspected disturbing factor. To meet this difficulty, the *method of constant range* is to be recommended. Here a range must first be determined by preliminary trials such that not over ninety in one hundred of the sounds in use can be heard by a normal ear. This range is scrupulously maintained for all pupils to be tested: the same test sounds are given to each pupil, and acuity, save in cases where hearing is so defective that nothing is heard at this distance, is determined by the percentage of sounds correctly reported. This method is specially desirable in the conduct of whisper tests.

Whichever method is followed, the following precautions should be observed: (1) One ear should be examined at a time; the other should be closed tightly, either by pressing the tragus into the meatus with the fleshy part of the ball of the thumb, or by plugging the meatus with a rubber stopper. (2) For the best results, however, a final test should be made with both ears open and with the pupil facing the examiner as in ordinary listening. (3) The pupil should be instructed to keep his eyes closed and his mouth closed (since opening the mouth alters the hearing). (4) The pupil must not be expected to listen continuously without knowing when to expect the stimulus, but must always be warned about 1.5 seconds before the sound is to be given. (5) The stimulus should occasionally be omitted after the warning signal is given, in order to make sure that the pupil really hears.

*Speech tests*, which may be conducted either by whispered or by vocalized speech, and either by the method of extreme, or by the method of constant range, have one fundamental advantage, in that they afford an unequivocal test of the hearing of conversational speech, whereas all instrumental tests are in some measure partial or equivocal. Speech tests, however, are difficult to employ for four reasons: (1) Articulate speech entails the use of a great variety and complex combination of pitches of different intensity and timbre, so that not all speech elements have the same normal range. (2) Examiners cannot guarantee uniformity of enunciation and intensity of stress from test to test. (3) Speech is markedly affected by the acoustic properties of the room in which the test is held. (4) Unavoidable noises are more likely to interfere with speech tests than with instrumental tests conducted at close range. To offset these difficulties it is desirable (1) to select carefully a set of test numerals, (2) to practice the examiner in enunciation (especially by adopting

the plan of whispering each test number at the end of an expiration of the breath), (3) to use the method of constant range, and (4) to select a quiet room and re-test doubtful cases under more favorable conditions or by other methods.

The *watch test* is the one most widely used. Its advantages are convenience, accessibility, and relatively short range. Its disadvantages are that it fails adequately to test capacity to hear speech, that its sounds give rise to a perception of rhythm, that its ticking is so familiar that illusions of hearing arise, and that different watches vary in intensity and quality of tick. For these last reasons various forms of acoumeters have been invented to replace the watch. Politzer's acoumeter is best known and extensively used in clinical work. In it the fall of a tiny hammer from a constant height upon a steel rod gives a brief tone (512 vibrations) of constant intensity. In use the examiner ascertains the maximal distance at which the subject can report correctly the number of "clicks" (two to five) that he makes. Lehmann's acoumeter allows variations in the intensity of its stimulus (a small steel shot dropped from varying heights upon a metal, glass, or cardboard shelf), so that it may be employed within the limits of an ordinary room and at a constant range.

To exclude disturbing noises, several experimenters have contrived instruments in which the stimulus is a click produced in a telephone receiver held close to the ear; the intensity is varied by introducing more or less resistance in the circuit. The best known of these instruments is Seashore's audiometer (*q.v.*), which has been extensively used by him and by others, especially by Smedley and MacMillan in the investigations of the Bureau of Child Study and Pedagogic Investigation connected with the Chicago public schools.

Most tests of hearing yield only relative results, *i.e.*, the acuity of a given pupil can be stated only with reference to the average performance of his mates under the particular conditions (make of watch, voice of teacher, size of room, arrangements of furniture, etc.) which prevailed in the test. Divergence in the results of hearing tests is due in part to this absence of standardization. What one examiner deems normal another may rank as defective.

A rough preliminary test of hearing may be made by placing all the pupils in a room at the limit of the ordinary classroom distance (32 feet), directing them in a whisper to perform some unusual movement, such as placing the right forefinger on the palm of the left hand. Note those who fail to respond or who do so in evident imitation of others. Or use a series of two-place whispered numbers, and let each pupil record them with pencil and paper. G. M. W.

**EAR TRAINING.**—Special exercises in ear training are given in schools to increase the power of discriminating among sounds. Such work is usual in the teaching of music. It is also used in teaching children to read, more particularly beginners and foreigners. Such exercises have been highly artificial and formal in nature. They are much less used than hitherto, the teacher relying for the requisite practice upon the recurrence of the difficult sounds in words, phrases, and other natural thought units rather than in specially invented devices. **EARLHAM COLLEGE, RICHMOND, IND.**—A coeducational institution which grew out of a school established in 1847 and organized as a college in 1859. In the promotion of advanced practical instruction in science Earlham College was one of the first institutions in the West. The institution is controlled by its founders, the orthodox Friends. Admission to the college is by certificate or examination based on a four years' high school course. Degrees of Bachelor of Arts and Bachelor of Science are conferred on completion of a four years' course, including prescribed subjects, a major subject, and elective subjects. The master's degree is given on one year's postgraduate work in residence. Professional work for teachers is also offered as well as courses in music. The college is located on a campus, forty acres in extent, and includes eight buildings used for recitations and dormitories. The productive funds of the institution amount (1911) to \$350,000, and the total income, including tuition fees, to \$41,867. The enrollment of students, including summer school, was 538 in 1909-1910. There is a faculty of thirty members.

**EARLY CHRISTIAN SCHOOLS.** — See CHRISTIAN EDUCATION IN THE EARLY CHURCH.

**EARLY, JOHN** (1814-1874). — Jesuit educator; was president of Holy Cross College at Worcester, Mass., founder and first president of St. Ignatius College at Baltimore, and president of Georgetown College at Washington, D. C. W. S. M.

**EAST INDIA SERVICE, TRAINING FOR.** — See PUBLIC SERVICE, TRAINING FOR.

**EASTBOURNE COLLEGE.** — See GRAMMAR SCHOOLS, ENGLISH; COLLEGES, ENGLISH; PUBLIC SCHOOLS.

**EASTBROOK, JOSEPH** (1820-1894). — A Michigan educator, educated in the public schools and at Oberlin College. He was principal of the schools at Ypsilanti (1853-1858), superintendent of the schools of East Saginaw (1858-1871), principal of the Michigan State Normal School at Ypsilanti (1871-1880), president of Olivet College (1880-1886), and state superintendent of schools in Michigan (1886-1890). W. S. M.

**EASTERN COLLEGE, MANASSAS, VA.** — A coeducational institution maintaining a college of liberal arts, teachers' training department, an academy, and schools of expression, music, commerce, and fine arts. Admission to the college is by certificate from an approved school or by examination. The degree of A. B. is conferred on completion of a four years' course. A postgraduate course leading to the M. A. is also offered. There are twenty-three members on the faculty.

**EASTMAN, HARVEY GRIDLEY** (1832-1878). — Founder of a chain of commercial schools in the United States, and for many years president of the Eastman Business College at Poughkeepsie. His first commercial school was founded at St. Louis in 1855.

W. S. M.

See COMMERCIAL EDUCATION.

**EATON, AMOS** (1777-1842). — Scientist and first president of Rensselaer Polytechnic Institute; was graduated from Williams College in 1799, and was for several years lecturer on science at that institution. He was president of the Rensselaer Institute at Troy from 1824 to 1842, and was the author of textbooks on botany, zoology, physics, and geology, and numerous scientific works. W. S. M.

**EATON, JOHN** (1829-1906). — Second commissioner of education of the United States, born at Sutton, N. H., the 5th of December, 1829. He was educated at Thetford Academy and Dartmouth College, where he was graduated in 1854, subsequently completing a course

at the Andover Theological Seminary. He was teacher and principal of schools at Cleveland (1854-1856), superintendent of schools at Toledo (1856-1859), served in the civil war, attaining the rank of brigadier-general, state superintendent of schools in Tennessee (1867-1869), and United States Commissioner of Education (1871-1886). Besides his writings in the annual reports of the Bureau of Education, he wrote a history of Thetford Academy, and numerous papers on the education of the freedmen. He died in 1906. W. S. M.

**EATON, NATHANIEL** (1609-1660). — The first professor in Harvard College, and acting president (master) until the appointment of President Dunster. He had previously been engaged in secondary school work in Massachusetts. W. S. M.

See HARVARD UNIVERSITY.

**EBBINGHAUS, HERMANN** (1850-1909). — One of the pioneers in the study of experimental psychology. After an education in the gymnasium of his own town, Barmen, he studied at Bonn, Halle, and Berlin, and after serving in the army during the Franco-German War took his Ph. D. degree at Bonn in 1873 with a dissertation on *Hartmann's Philosophy of the Unconscious*. Although his early studies had been in pure philosophy, and he had as private docent at Berlin lectured on the history of philosophy, it was soon evident that his main interest lay in the field of experimental psychology, which, he always insisted, was a branch of the natural sciences rather than philosophy, as it had hitherto been classed. In 1886 he became extraordinary professor at Berlin, in 1894 professor at Breslau, and in 1905 professor at Halle. His most important contribution to psychology was the application of quantitative measurement to mental phenomena, especially memory. In 1890 he established the first important psychological journal in Germany, *Zeitschrift für Psychologie und Physiologie der Sinnesorgane*. His most important publications are *Über das Gedächtnis: Untersuchungen zur experimentellen Psychologie* (Leipzig, 1885); *Grundzüge der Psychologie* (Leipzig, 1897-1902); *Abriß der Psychologie* (Leipzig, 1907; trans., New York, 1908); *Über eine neue Methode zur Prüfung geistiger Fähigkeiten und ihre Anwendung bei Schulkindern* (in *Zeitschr. f. Psych.* Vol. 13, pp. 401-459), advocating the combination method for measuring intellectual ability.

**EBBINGHAUS' TEST.** — The German psychologist, Ebbinghaus (*q.v.*), called attention to the fact that most psychological tests deal with very restricted forms of mental activity. He suggested that a more general type

of mental activity could be called out and could be measured by presenting to the person to be tested a paragraph in which words were here and there left out. The filling in of the blanks in such a paragraph will require time, which will be shorter or longer according to the ability of the person being tested to apprehend the general meaning of the sentences and to supply the associated words necessary to complete this meaning. The degree of correctness with which the supplied words fill out the sense will also serve as a measure of intelligence.

**EBERHARD BETHUNIENSIS.** — A grammarian of Béthune in Artois. The writer of a Latin Grammar, called the *Graccismus*. It was written about 1212, and was in use in the schools until the time of Erasmus, who speaks of it as a textbook at Deventer in 1476. The importance attached to the *Graccismus*, along with the *Doctrinale* of Alexander de Villa Dei, may be proved by the fact that they were both prescribed as textbooks in universities, e.g. in the statutes of Toulouse, 1328, of Paris, 1366, of Vienna, 1389. As early printed the work is entitled: *Graccismus, de figuris et octo partibus orationis sive grammaticae regulae versibus latinis explicatae, cum expositionibus Joannis Vincentii Metulini* (Paris, 1487). The *Graccismus*, as well as the *Doctrinale*, was already glossed before 1270. Vergil is the author chiefly quoted, and next follow Ovid, Lucan, Horace, Statius, and Terence. The amount of Greek dealt with is very small, viz. chiefly in chapters of the technical figures of speech and in ch. viii words derived from the Greek. Eberhard has been suggested as the author of (1) the well-known medieval work *Labyrinthus*; (2) *Anti-haereticus* (one of three joint writings); and several other works.

**ECKOFF, WILLIAM JULIUS** (1853-1908). — Educational writer, educated in Germany and at New York University and Columbia University; principal of a college in Nicaragua; professor of pedagogy in the University of Illinois; author of *Herbart's A B C of Sense-perception*, and numerous articles in educational journals.

W. S. M.

**ECLECTIC METHOD.** — A method which combines the essential elements of several systems of instruction. The term is more particularly applied to mixed or combination methods of teaching reading. In teaching reading to beginners there are many special methods, such as the word method, sentence method,

phonetic method, etc. An eclectic method would follow no one of these exclusively, but would select and appropriate what is considered most valuable in each.

H. S.

See READING; TEACHING BEGINNERS; COMBINED METHOD.

**ÉCOLE DES ROCHES.** — One of the new schools (*q.v.*) established in France by M. Edmond Demolins in 1899. It is situated on a large estate near the rocky cliffs of Normandy whence it derives its name. This school and others that followed its example arose as a protest against the secondary school system in France, which to the leaders of the movement was not only too bureaucratic and uniform, but was entirely suppressive of the individual. M. Demolins outlined his scheme for a new school in a book, *L'Éducation Nouvelle*, published in 1898, and as a result was able to open his school in 1899 with fifty pupils. The aim of the school is "to make strong boys, independent in character and masters of themselves." The ideal is borrowed mainly from the English public schools and schools like Abbotsholme. Provision is made for constant personal relations between pupils and teachers on a basis of common interests. Physical culture, outdoor exercises, and hygiene form important features of the school; manual work both in and out of doors, visits to different industrial centers, may also be mentioned, as well as the emphasis laid on practical science work. The classics are postponed to the fifth year at school, and are taught mainly by the aid of translations. The pupils are encouraged to spend from three months to a year in England or Germany to learn foreign languages. In place of the barrack type of internat, home surroundings are reproduced. The *École des Roches* and others of this type, while successful in calling attention to the weaknesses of the French secondary school system before the recent reforms, have on the whole not met with any general response, — thus illustrating an educational truth that a system cannot be bodily transferred from one country to another with any degree of success.

**ECOLOGY.** — See BOTANY.

**ECONOMICS.—History.**—The science now known as Economics was for a long time called Political Economy. This term is due to a Frenchman—Montchrétien, Sieur de Watteville—who wrote in 1615 a book with that title, employing a term which had been used in a slightly different sense by Aristotle. During the Middle Ages economic questions were regarded very largely from the moral and theological point of view, so that the discussions of the day were directed rather to a consideration of what ought to be, than of what is.

The revolution of prices in the sixteenth century and the growth of capital led to great economic changes, which brought into the foreground, as of fundamental importance, questions of commerce and industry. Above all, the breakdown of the feudal system and the formation of national states emphasized the considerations of national wealth and laid stress on the possibility of governmental action in furthering national interests. This led to a discussion of economic problems on a somewhat broader scale,—a discussion now carried on, not by theologians and canonists, but by practical business men and by philosophers interested in the newer political and social questions. The emphasis laid upon the action of the State also explains the name Political Economy. Most of the discussions, however, turned on the analysis of particular problems, and what was slowly built up was a body of practical precepts rather than of theoretic principles, although, of course, both the rules of action and the legislation which embodied them rested at bottom on theories which were not yet adequately formulated.

The origin of the modern science of economics, which may be traced back to the third quarter of the eighteenth century, is due to three fundamental causes. In the first place, the development of capitalistic enterprise and the differentiation between the laborer and the capitalist brought into prominence the various shares in distribution, notably the wages of the laborer, the profits of the capitalist, and the rent of the landowner. The attempt to analyze the meaning of these different shares and their relation to national wealth was the chief concern of the body of thinkers in France known as *Physiocrats*, who also called themselves *Philosophes-Economistes*, or simply *Economistes*, of whom the court physician of Louis XVI, Quesnay, was the head, and who published their books in 1757–1780.

The second step in the evolution of economic science was taken by Adam Smith (*q.v.*). In the chair of philosophy at the University of Glasgow, to which Adam Smith was appointed in 1754, and in which he succeeded Hutcheson, it was customary to lecture on natural law in some of its applications to politics. Gradually, with the emergence of the more important economic problems, the same attempt to find

an underlying natural explanation for existing phenomena was extended to the sphere of industry and trade; and during the early sixties Adam Smith discussed these problems before his classes under the head of "police." Finally, after a sojourn in France and an acquaintance with the French ideas, Adam Smith developed his general doctrines in his immortal work, *The Wealth of Nations*, published in 1776. When the industrial revolution, which was just beginning as Adam Smith wrote, had made its influence felt in the early decades of the nineteenth century, Ricardo attempted to give the first thorough analysis of our modern factory system of industrial life, and this completed the framework of the structure of economic science which is now being gradually filled out.

The third element in the formation of modern economics was the need of elaborating an administrative system in managing the government property of the smaller German and Italian rulers, toward the end of the eighteenth century. This was the period of the so-called police state when the government conducted many enterprises which are now left in private hands. In some of the German principalities, for instance, the management of the government lands, mines, industries, etc., was assigned to groups of officials known as *chambers*. In their endeavor to elaborate proper methods of administration these chamber officials and their advisors gradually worked out a system of principles to explain the administrative rules. The books written, as well as the teaching chairs founded, to expound these principles came under the designation of the Chamber sciences (*Cameralia* or *Cameral-Wissenschaften*)—a term still employed to-day at the University of Heidelberg. As Adam Smith's work became known in Germany and Italy by translations, the chamber sciences gradually merged into the science of political economy.

Finally, with the development of the last few decades, which has relegated to the background the administrative and political side of the discipline, and has brought forward the purely scientific character of the subject, the term Political Economy has gradually given way to Economics.

#### **Development of Economic Teaching.**—

*Europe.*—As has been intimated in the preceding section, the first attempts to teach what we to-day would call economics were found in the European universities which taught natural law, and in some of the Continental countries where the chamber sciences were pursued. The first independent chairs of political economy were those of Naples in 1753, of which the first incumbent was Genovesi, and the professorship of cameral science at Vienna in 1763, of which the first incumbent was Sonnenfels. It was not, however, until the nineteenth century that political economy was generally introduced as a university discipline. When

the new University of Berlin was created in 1810, provision was made for teaching in economics, and this gradually spread to the other German universities. In France a chair of economics was established in 1830 in the Collège de France, and later on in some of the technical schools; but economics did not become a part of the regular university curriculum until the close of the seventies, when chairs of political economy were created in the faculties of law, and not, as was customary in the other Continental countries, in the faculties of philosophy. In England the first professorship of political economy was that instituted in 1805 at Haileybury College, which trained the students for the East India service. The first incumbent of this chair was Malthus. At University College, London, a chair of economics was established in 1828, with McCulloch as the first incumbent; and at Dublin a chair was founded in Trinity College in 1832 by Archbishop Whately; at Oxford a professorship was established in 1825, with Nassau W. Senior as the first incumbent. His successors were Richard Whately (1830), W. F. Lloyd (1836), H. Merivale (1838), Travers Twiss (1842), Senior (1847), G. K. Richards (1852), Charles Neate (1857), Thorold Rogers (1862), Bonamy Price (1868), Thorold Rogers (1888), and F. Y. Edgeworth (1891). At Cambridge the professorship dates from 1863, the first incumbent being Henry Fawcett, who was followed by Alfred Marshall in 1884 and by A. C. Pigou in 1908. In all these places, however, comparatively little attention was paid at first to the teaching of economics, and it was not until the close of the nineteenth century and the beginning of the twentieth that any marked progress was made, although the professorship at King's College, London, dates back to 1859, and that at the University of Edinburgh to 1871. Toward the close of the nineteenth century, chairs in economics were created in the provincial universities, especially at Birmingham, Manchester, Liverpool, Sheffield, Bristol, Durham, and the like, as well as in Scotland and Wales; and a great impetus to the teaching of economics was given by the foundation, in 1895, of the London School of Economics, which has recently been made a part of the University of London.

*United States.* — Economics was taught at first in the United States, as in England, by incumbents of the chair of philosophy; but no especial attention was paid to the study, and no differentiation of the subject matter was made. The first professorship in the title of which the subject is distinctively mentioned was that instituted at Columbia College, New York, where John McViekar, who had previously lectured on the subject under the head of philosophy, was made professor of moral philosophy and political economy in 1819. In order to commemorate this fact, Columbia University established some years ago the

McViekar professorship of political economy. The second professorship in the United States was instituted at South Carolina College, Columbia, S. C., where Thomas Cooper, professor of chemistry, had the subject of political economy added to the title of his chair in 1826. A professorship of similar sectional influence was that in political economy, history, and metaphysics filled in the College of William and Mary in 1827, by Thomas Roderick Dew (1802-1846). The separate professorships of political economy, however, did not come until after the Civil War. Harvard established a professorship of political economy in 1871; Yale in 1872; and Johns Hopkins in 1876.

The real development of economic teaching on a large scale began at the close of the seventies and during the early eighties. The newer problems bequeathed to the country by the Civil War were primarily economic in character. The rapid growth of industrial capitalism brought to the front a multitude of questions, whereas before the war well-nigh the only economic problems had been those of free trade and of banking, which were treated primarily from the point of view of partisan politics. The newer problems that confronted the country led to the exodus of a number of young men to Germany, and with their return at the end of the seventies and beginning of the eighties, chairs were rapidly multiplied in all the larger universities. Among these younger men were Patten and James, who went to the University of Pennsylvania; Clark, of Amherst and later of Columbia; Farnam and Hadley of Yale; Taussig of Harvard; H. C. Adams of Michigan; Mayo-Smith and Seligman of Columbia; and Ely of Johns Hopkins. The teaching of economics on a university basis at Johns Hopkins under General Francis A. Walker helped to create a group of younger scholars who soon filled the chairs of economics throughout the country. In 1879 the School of Political Science at Columbia was inaugurated on a university basis, and did its share in training the future teachers of the country. Gradually the teaching force was increased in all the larger universities, and chairs were started in the colleges throughout the length and breadth of the land.

At the present time, most of the several hundred colleges in the United States offer instruction in the subject, and each of the larger institutions has a staff of instructors devoted to it. At institutions like Columbia, Harvard, Yale, Chicago, and Wisconsin there are from six to ten professors of economics and social science, together with a corps of lecturers, instructors, and tutors.

**Teaching of Economics in the American Universities.** — The present-day problems of the teaching of economics in higher institutions of learning are seriously affected by the transition stage through which these institutions are passing. In the old American college,

when economics was introduced it was taught as a part of the curriculum designed to instill general culture. As the graduate courses were added, the more distinctly professional and technical phases of the subject were naturally emphasized. As a consequence, both the content of the course and the method employed tended to differentiate. But the unequal development of our various institutions has brought great unclarity into the whole pedagogical problem. Even the nomenclature is uncertain. In one sense graduate courses may be opposed to undergraduate courses; and if the undergraduate courses are called the college courses, then the graduate courses should be called the university courses. The term "university," however, is coming more and more, in America at least, to be applied to the entire complex of the institutional activities, and the college proper or undergraduate department is considered a part of the university. Furthermore, if by university courses as opposed to college courses we mean advanced, professional, or technical courses, a difficulty arises from the fact that the latter year or years of the college course are tending to become advanced or professional in character. Some institutions have introduced the combined course, that is, a combination of so-called college and professional courses; other institutions permit students to secure their baccalaureate degree at the end of three or even two and a half years. In both cases, the last year of the college will then cover advanced work, although in the one case it may be called undergraduate, and in the other graduate, work.

The confusion consequent upon this unequal development has had a deleterious influence on the teaching of economics, as it has in many other subjects. In all our institutions we find a preliminary or beginners' course in economics, and in our largest institutions we find some courses reserved expressly for advanced or graduate students. In between these, however, there is a broad field, which, in some institutions, is cultivated primarily from the point of view of graduates, in others from the point of view of undergraduates, and in most cases is declared to be open to both graduates and undergraduates. This is manifestly unfortunate. For, if the courses are treated according to advanced or graduate methods, they do not fulfill their proper function as college studies. On the other hand, if they are treated as undergraduate courses, they are more or less unsuitable for advanced or graduate students. In almost all of the American institutions the same professors conduct both kinds of courses. In only one institution, namely, at Columbia University, is the distinction between graduate and undergraduate courses in economics at all clearly drawn, although even there not with precision. At Columbia University, of the ten professors who are conducting courses in economics and

social science, one half have seats only in the graduate faculties, and do no work at all in the college or undergraduate department; but even there, these professors give a few courses, which, while frequented to an overwhelming extent by graduate students, are open to such undergraduates as may be declared to be advanced students.

It is necessary, therefore, to distinguish, in principle at least, between the undergraduate or college courses properly so-called, and the university or graduate courses. For it is everywhere conceded that at the extremes, at least, different pedagogical methods are appropriate.

*The College or Undergraduate Instruction.*—Almost everywhere in the American colleges there is a general or preliminary or foundation course in economics. This ordinarily occupies three hours a week for the entire year, or five hours a week for the semester, or half year, although the three-hour course in the fundamental principles occasionally continues only for a semester. The foundation of such a course is everywhere textbook work, with oral discussion, or quizzes, and frequent tests. Where the number of students is small, this method can be effectively employed; but where, as in our larger institutions, the students attending this preliminary course are numbered by the hundreds, the difficulties multiply. Various methods are employed to solve these difficulties. In some cases the class attends as a whole at a lecture which is given once a week by the professor, while at the other two weekly sessions the class is divided into small sections of from twenty to thirty, each of them in charge of an instructor who carries on the drill work. In a few instances, these sections are conducted in part by the same professor who gives the lecture, in part by other professors of equal grade. In other cases where this forms too great a drain upon the strength of the faculty, the sections are put in the hands of younger instructors or drill masters. In other cases, again, the whole class meets for lecture purposes twice a week, and the sections meet for quiz work only once a week. Finally, the instruction is sometime carried on entirely by lectures to the whole class, supplemented by numerous written tests.

While it cannot be said that any fixed method has yet been determined, there is a growing consensus of opinion that the best results can be reached by the combination of one general lecture and two quiz hours in sections. The object of the general lecture is to present a point of view from which the problems may be taken up, and to awaken a general interest in the subject among the students. The object of the section work is to drill the students thoroughly in the principles of the science; and for this purpose it is important in a subject like economics to put the sections as far

as possible in the hands of skilled instructors rather than of recent graduates.

Where additional courses are offered to the undergraduates, they deal with special subjects in the domain of economic history, statistics, and practical economies. In many such courses good textbooks are now available, and especially in the last class of subjects an attempt is being made here and there to introduce the case system as utilized in the law schools. This method is, however, attended by some difficulties, arising from the fact that the materials used so quickly become antiquated and do not have the compelling force of precedent, as is the case in law. In the ordinary college course, therefore, chief reliance must still be put upon the independent work and the fresh illustrations that are brought to the classroom by the instructor.

In some American colleges the mistake has been made of introducing into the college curriculum methods that are suitable only to the university. Prominent among these are the exclusive use of the lecture system, and the employment of the so-called seminar. This, however, only tends to confusion. On the other hand, in some of the larger colleges the classroom work is advantageously supplemented by discussions and debates in the economics club, and by practical exercises in dealing with the current economic problems as they are presented in the daily press.

In most institutions the study of economics is not begun until the sophomore or the junior year, it being deemed desirable to have a certain maturity of judgment and a certain preparation in history and logic. In some instances, however, the study of economics is undertaken at the very beginning of the college course, with the resulting difficulty of inadequately distinguishing between graduate and undergraduate work.

Another pedagogical question which has given rise to some difficulty is the sequence of courses. Since the historical method in economics became prominent, it is everywhere recognized that some training in the historical development of economic institutions is necessary to a comprehension of existing facts. We can know what is very much better by grasping what has been and how it has come to be. The point of difference, however, is as to whether the elementary course in the principles should come first and be supplemented by a course in economic history, or whether, on the contrary, the course in economic history should precede that in the principles. Some institutions follow one method, others the second; and there are good arguments on both sides. It is the belief of the writer, founded on a long experience, that on the whole the best results can be reached by giving as introductory to the study of economic principles a short survey of the leading points of economic history. In a few of the modern textbooks this plan is

intentionally followed. Taking it all in all, it may be said that college instruction in economics is now not only exceedingly widespread in the United States, but continually improving in character and methods.

*University or Graduate Instruction.* — The university courses in economics are designed primarily for those who either wish to prepare themselves for the teaching of economics or who desire such technical training in methods or such an intimate acquaintance with the more developed matter as is usually required by advanced or professional students in any discipline. The university courses in the larger American institutions which now take up every important subject in the discipline, and which are conducted by a corps of professors, comprise three elements: first, the lectures of the professor; second, the seminar or periodical meeting between the professor and a group of advanced students; third, the economics club, or meeting of the students without the professor.

(1) *The Lectures:* In the university lectures the method is different from that in the college courses. The object is not to discipline the student, but to give him an opportunity of coming into contact with the leaders of thought and with the latest results of scientific advance on the subject. Thus no roll of attendance is called, and no quizzes are enforced and no periodical tests of scholarship are expected. In the case of candidates for the Ph.D. degree, for instance, there is usually no examination until the final oral examination, when the student is expected to display a proper acquaintance with the whole subject. The lectures, moreover, do not attempt to present the subject in a dogmatic way, as is more or less necessary in the college courses, but, on the contrary, are designed to present primarily the unsettled problems and to stimulate the students to independent thinking. The university lecture, in short, is expected to give to the student what cannot be found in the books on the subject.

(2) *The Seminar:* Even with the best of will, however, the necessary limitations prevent the lecturer from going into the minute details of the subject. In order to provide opportunity for this, as well as for a systematic training of the advanced students in the method of attacking this problem, periodical meetings between the professor and the students have now become customary under the name of the seminar, introduced from Germany. In most of our advanced universities the seminar is restricted to those students who are candidates for the degree of Doctor of Philosophy, although in some cases a preliminary seminar is arranged for graduate students who are candidates for the degree of Master of Arts. Almost everywhere a reading knowledge of French and German is required. In the United States, as on the European continent generally, there are

minor variations in the conduct of the seminar. Some professors restrict the attendance to a small group of most advanced students, of from fifteen to twenty-five; others virtually take in all those who apply. Manifestly the personal contact and the "give and take," which are so important a feature of the seminar, become more difficult as the numbers increase. Again, in some institutions each professor has a seminar of his own; but this is possible only where the number of graduate students is large. In other cases the seminar consists of the students meeting with a whole group of professors. While this has a certain advantage of its own, it labors under the serious difficulty that the individual professor is not able to impress his own ideas and his own personality so effectively on the students; and in our modern universities students are coming more and more to attend the institution for the sake of some one man with whom they wish to study. Finally, the method of conducting the seminar differs in that in some cases only one general subject is assigned to the members for the whole term, each session being taken up by discussion of a different phase of the general subject. In other cases a new subject is taken up at every meeting of the seminar. The advantage of the latter method is to permit a greater range of topics, and to enable each student to report on the topic in which he is especially interested, and which, perhaps, he may be taking up for his doctor's dissertation. The advantage of the former method is that it enables the seminar to enter into the more minute details of the general subject, and thus to emphasize with more precision the methods of work. The best plan would seem to be to devote half the year to the former method, and half the year to the latter method.

In certain branches of the subject, as, for instance, statistics, the seminar becomes a laboratory exercise. In the largest universities the statistical laboratory is equipped with all manner of mechanical devices, and the practical exercises take up a considerable part of the time. The statistical laboratories are especially designed to train the advanced student in the methods of handling statistical material.

(3) The Economics Club: The lecture work and the seminar are now frequently supplemented by the economics club, a more informal meeting of the advanced students, where they are free from the constraint that is necessarily present in the seminar, and where they have a chance to debate, perhaps more unreservedly, some of the topics taken up in the lectures and in the seminar, and especially the points where some of the students dissent from the lecturer. Reports on the latest periodical literature are sometimes made in the seminar and sometimes in the economics club; and the club also provides an opportunity for inviting distinguished outsiders in the various

subjects. In one way or another, the economics club serves as a useful supplement to the lectures and the seminar, and is now found in almost all the leading universities.

In reviewing the whole subject we may say that the teaching of economics in American institutions has never been in so satisfactory condition as at present. Both the instructors and the students are everywhere increasing in numbers; and the growing recognition of the fact that law and politics are so closely interrelated with, and so largely based on, economics, has led to a remarkable increase in the interest taken in the subject and in the facilities for instruction.

E. R. A. S.

**Economics.**—**In the Schools.**—This subject has been defined as the study of that which pertains to the satisfaction of man's material needs,—the production, preservation, and distribution of wealth. As such it would seem fundamental that the study of economics should find a place in those institutions which prepare children to become citizens,—the elementary and high schools. Some of the truths of economics are so simple that even the youngest of school children may be taught to understand them. As a school study, however, economics up to the present time has made far less headway than civics (*q.v.*). Its introduction as a study even in the colleges was so gradual and so retarded that it could scarcely be expected that educators would favor its introduction in the high schools.

Previous to the appearance, in 1894, of the *Report of the Committee of Ten* of the National Educational Association on Secondary Education, there had been much discussion on the educational value of the study of economics. In that year Professor Patten had written a paper on *Economics in Elementary Schools*, not as a plea for its study there, but as an attempt to show how the ethical value of the subject could be made use of by teachers. The *Report*, however, came out emphatically against formal instruction in political economy in the secondary school, and recommended "that, in connection particularly with United States history, civil government, and commercial geography, instruction be given in those economic topics, a knowledge of which is essential to the understanding of our economic life and development" (pp. 181-183). This view met with the disapproval of many teachers. In 1895 President Thwing of Western Reserve University, in an address before the National Educational Association on *The Teaching of Political Economy in the Secondary Schools*, maintained that the subject could easily be made intelligible to the young. Articles or addresses of similar import followed by Commons (1895), James (1897), Haynes (1897), Stewart (1898), and Taussig (1899). Occasionally a voice was raised against its formal study in the high schools. In the *School Review* for January, 1898, Professor Dixon of Dartmouth said that

its teaching in the secondary schools was "unsatisfactory and unwise." On the other hand, Professor Stewart of the Central Manual Training School of Philadelphia, in an address in April, 1898, declared the *Report of the Committee of Ten* "decidedly reactionary," and prophesied that political economy as a study would be put to the front in the high school. In 1899 Professor Clow of the Oshkosh State Normal School published an exhaustive study of the subject of *Economics as a School Study*, going into the questions of its educational value, its place in the schools, the forms of the study, and the methods of teaching. His researches serve to show that the subject was more commonly taught in the high schools of the Middle West than in the East. (Compare with the article on Civics.)

Since the publication of his work the subject of economics has gradually made its appearance in the curricula of many Eastern high schools. It has been made an elective subject of examination for graduation from high schools by the Regents of New York State, and for admission to college by Harvard University. Its position as an elective study, however, has not led many students to take it except in commercial high schools, because in general it may not be used for admission to the colleges.

Its great educational value, its close touch with the pupils' everyday life, and the possibility of teaching it to pupils of high school age are now generally recognized. A series of articles in the National Educational Association's *Proceedings* for 1901, by Spiers, Gunton, Halleck, and Vincent bear witness to this. The October, 1910, meeting of the New England History Teachers' Association was entirely devoted to a discussion of the Teaching of Economics in Secondary Schools, and Professors Taussig and Haynes reiterated views already expressed. Representatives of the recently developed commercial and trade schools expressed themselves in its favor.

Suitable textbooks in the subject for secondary schools have not kept pace with its spread in the schools. Laughlin, Macvane, and Walker published books somewhat simply expressed; but later texts have been too collegiate in character. There is still needed a text written with the secondary school student constantly in mind, and preferably by an author who has been dealing with students of secondary school age. The methods of teaching, *mutatis mutandis*, have been much the same as those pursued in civics (*q.v.*). The mere cramming of the text found in the poorest schools gives way in the best schools to a study and observation of actual conditions in the world of to-day. In the latter schools the teacher has been well trained in the subject, whereas in the former it is given over only too frequently to teachers who know little more about it than that which is in the text.

**ECUADOR, EDUCATION IN.**—Ecuador, republic; area, 116,000 square miles; population, 1,205,000. By the constitution of 1884 and subsequent modifications, of which the latest was adopted in 1907, Ecuador comprises sixteen provinces administered by governors appointed by the President of the Republic. The earlier education laws provided for a public system of education under the supreme direction of the minister of public instruction. The individual provinces were required to provide primary schools which should be free, and attendance at the same compulsory for all children not under private instruction. The costs of primary education are borne by state, provincial, and municipal funds. Secondary and higher education were also placed under the general direction of the minister. The conditions of the country, however, have prevented rapid and substantial progress as regards the provision of primary schools, and with the exception of a few national colleges, or *liceos*, secondary education has been left to church establishments. By the constitution, the Roman Catholic religion is declared to be that of the nation, but all denominations are tolerated, and the national church is subject to the State; members of the episcopacy must be citizens of Ecuador, and the educational institutions of the church must conform to legal requirements. The control over education has been exercised by the minister, chiefly through regulations pertaining to courses of study, standards for government diplomas, etc., and to corrective measures based upon the annual reports of the directors of provincial institutions and primary schools.

According to the latest reports there are 1088 primary schools, 35 secondary schools (*liceos*), and 9 institutions for higher education. The number of teachers in primary and secondary schools was about 1500 in 1908, and the number of pupils 68,380, or a little less than six per cent of the population. In comparing the low rate of school attendance in Ecuador with that of the leading nations, it must be remembered that a

large part of the population consists of Indians; about 400,000 are of mixed race; and a relatively small proportion are unmixed, being of European birth or origin. The system of government and of school administration is the work, in the main, of the mixed race, and affords interesting proof of their political aspirations and purposes.

At present the reform of education engages the attention of both central and provincial authorities. The law of September 24, 1906, providing for the decentralization of the primary system, was intended to incite the local authorities to a deeper sense of responsibility and more earnest efforts in respect to the provision and maintenance of public schools. But the policy is regarded by many as premature. For one reason, it does not conform to the established centralization of the fiscal system of the country, which precludes absolute autonomy on the part of the provinces. At the same time, the policy exposes the state to the perils of neglect and indifference on the part of backward provinces. A vigorous system of state supervision seems to be the only safeguard against glaring inequalities of school provision in the different divisions. Among reforms proposed in the general exposition of the law are the increase of primary schools, the enforcement of the compulsory law, and the improvement of the teaching force. The law provides that rural schools shall be established and maintained by the owners of every estate where there are twenty or more children; this would require a minute census of Indians, who are chiefly employed on the estates, and the preparation of tables and registers showing both the rich proprietors, who are able to maintain schools by themselves, and the small owners, who can support them by contributions *pro rata*. In the more progressive communities problems of school sanitation are exciting attention, and a few municipalities have taken measures for the medical inspection of schools. Normal schools are included in the reform measures, and the principles of modern pedagogy and equipment for the pursuit of manual training and agriculture are transforming the spirit and method of their training.

As regards secondary schools the need of radical reforms is clearly recognized. The rector of the *Colegio Bolívar* in a recent report to the minister of public instruction proposes certain changes in the system with a view to making secondary instruction a continuation of primary. "Secondary instruction ought," he says, "to give a general training based on the study of the native language and foreign languages, and the sciences, and should be a development of the primary program — keeping in mind that all knowledge is sterile if it has no application in practical life in the arts and business. Education should prepare the pupil for any career, whether scientific, literary, industrial, commercial, or pedagogical." He proposes the

introduction of a modern course of study parallel with the lower section of the established secondary course and leading to an advanced section in which choice will be allowed between a commercial course and a technical course. In support of his proposal he cites the example of Switzerland. The rector of the national college, Mijia, in Quito, the highest type of secondary school in the state, urges, also, the institution of a technical and scientific course equivalent to the humanistic, and crowned, like the latter, with the bachelor's diploma. Thus it appears that the problems of secondary education in Ecuador are the same as those which have been agitating the principal countries during the last decade.

Quito is the seat of two normal schools, one for men, the other for women, of the national school of fine arts, of the national conservatory of music, and of the principal university (*Universidad Central*). This university comprises the faculties of law (course six years); medicine (seven years); pharmacy (five years); and science (three years). Students in the faculty of science who graduate with high honors may be sent abroad at government expense to perfect themselves in particular branches of science. The general plan of studies for the Central University is the same as for the two remaining universities, Guayaquil and Azuay.

EDESSA, SCHOOLS OF. — See CATECHETICAL SCHOOLS.

EDGEWORTH, MARIA (1767-1849). — The novelist, daughter of Richard Lovell Edgeworth (*q.v.*), was born at Black Bourton, fourteen miles from Oxford. She attended private schools, and, while her father remained in Ireland, spent her vacations with Thomas Day (*q.v.*), the great friend of her father, and author of *Sandford and Merton*. In 1782 Miss Edgeworth returned to Edgeworthstown in Ireland, where she spent the greater part of her life. For her brothers and sisters she began to write children's stories, at first without any idea of publication, and written down on a slate to be retained or not according to the approval or disapproval of her young audience. Such was the origin of the collections published under the titles of *Parent's Assistant* (first volume in 1796; in 6 vols. in 1800); *Early Lessons* (1801), *Moral Tales* (1801), and *Popular Tales* (1804). The first of these may

be described as an appendix to *Practical Education*, in the production of which she had assisted her father; a work with a similar purpose in view of popularizing the educational theories contained in *Practical Education*, a modification of Rousseau's *Emile*, was *Harry and Lucy*, written by the father and daughter. These stories are didactic in tone, and aim to point some moral; the triumph of virtue and the downfall of evil form the central theme of the majority. They enjoyed a wide and long popularity, but the probability is that, except with very young children, they would now be found somewhat dull. Miss Edgeworth interested herself not only in the education of her brothers and sisters, to whom she was warmly attached, but along with her father paid no little attention to the education of the children on the Edgeworth estate. Lockhart, the biographer and son-in-law of Sir Walter Scott, in describing a visit paid to Edgeworthstown, says: "Here we found neither mud hovels nor naked peasantry. Here there was a very large school in the village, of which masters and pupils were, in a nearly equal proportion, Protestants and Roman Catholics, the Protestant squire making it a regular part of his daily business to visit the scene of their operations, and strengthen authority, and enforce discipline by his personal superintendence." The *Memoirs* of her father, which she edited, contain a good account of the educational theories and interests of her father, in which she undoubtedly shared. Her views on female education are contained in a very early work, *Letters to Literary Ladies*, written at her father's orders in 1795. This work was a defense of the education of women. It is interesting to note that her last work, *Orlandino*, as her first, was written for the amusement of children. Of her novels, all of which are intended to convey a moral purpose, it is not necessary here to speak; they met with immediate success, and for thirty-four years (*Castle Rackrent*, 1800, *Iden*, 1834), Miss Edgeworth remained actively before the public.

LAWLESS, E. *Maria Edgeworth*. (New York, 1904.)

**EDGEWORTH, RICHARD LOVELL** (1741-1817). — Author, experimentalist, and educational reformer; member of a distinguished family which, English in origin, had settled in Ireland in the reign of Queen Elizabeth. The training which he received from his mother during his childhood at Edgeworthstown greatly influenced his character and intellectual interests. His first instruction in Latin was received from a neighboring clergyman, Patrick Hughes, who had been one of the teachers of Oliver Goldsmith. In 1752 he was sent to Dr. Lydiat's school in Warwick, but

afterwards to Drogheda School, which, under Dr. Norris, was then reputed the best in Ireland, and subsequently to a school at Longford. In his seventeenth year he entered into residence at Trinity College, Dublin, where he spent six months in idleness and dissipation. Consequently his father removed him to the University of Oxford, where he entered Corpus Christi College as a gentleman commoner in October, 1761. While still an undergraduate and under age, he married Anna Maria, the daughter of Paul Elers, a gentleman of German descent. Maria Edgeworth was a daughter of this marriage, which was not a happy one. At Hare Hatch, under the influence of *Emile*, he determined to educate his son according to the system of Rousseau (*q.v.*), and the result of the experiment continued for several years. It was during his residence at Hare Hatch that Edgeworth became an intimate friend of Thomas Day (*q.v.*), another admirer of Rousseau and subsequently the author of *Sandford and Merton*. Edgeworth also was admitted into the circle of scientific men then resident in Birmingham and the Potteries — Bolton, Watt, Darwin, and Josiah Wedgwood. He was also intimate with a brilliant society of literary and scientific men in London — John Hunter, Sir Joseph Banks, Maskelyne, Captain Cook, Smeaton, and Ramsden, the optician. In 1771 Edgeworth went with Day, for more than a year, to France, thus becoming intimate with French thought and feeling and with some of the intellectual leaders of French society.

Edgeworth was four times married, and had living with him a numerous family (four sons and five daughters, some grown up, some very young) by his different wives. After his fourth marriage, the two sisters of his second and third wives continued to reside with him. Nothing, however, clouded the affection which united this extraordinary household, in which every intellectual and public interest was keenly sustained, and in which all the circumstances and occupations of a brisk and happy family life were skillfully made use of in the work of education.

From 1782, as a resident landlord on his Irish estates, Edgeworth devoted much thought to the improvement of the condition of the poor upon his estate and in his neighborhood, and to educational reform as the surest means of increasing the security and happiness of the people. In 1788 the Lord Lieutenant had appointed Commissioners to inquire into all schools of public or charitable foundation and all grants or funds for the purpose of education in Ireland. The investigations of these commissioners drew public attention to the problem of national education. In 1799, as a member of the last Irish Parliament, Edgeworth moved: "That the state of public education in Ireland is highly defective and requires the interposition of Parliament; that one or more schools should be established in each parish; that the masters for schools should undergo examinations, obtain

certificates of their conduct, etc., and be licensed annually by the diocesan; and that one or more visitors be appointed to inspect schools in each parish one or more times in each year." Leave was granted to introduce a Bill based on these resolutions, but it did not become an act of Parliament. After the Act of Union in 1800 (which Edgeworth believed would be ultimately advantageous to Ireland, but against which he voted in detestation of the means adopted in carrying it), Edgeworth was appointed, in 1806, by the Duke of Bedford, the Viceroy, to serve on a Board of Commissioners to inquire into the education of the people of Ireland. The Board, the members of which were unpaid, sat from 1806 to 1811. At the request of his colleagues on this Commission Edgeworth submitted a memorandum in which he outlined a policy for Irish elementary education. Many of Edgeworth's recommendations were adopted in 1831, when the Board of Commissioners of National Education in Ireland was established.

Edgeworth was intensely interested in the science and art of teaching and in the principles of education. "I claim for my father," wrote his daughter Maria, "the merit of having been the first to recommend by example and precept what Bacon would call the experimental method in education." He was assiduous in instructing the children of his own family, for whom he printed *Harry and Lucy*, the aim of which was to diffuse through a story the first principles of morality, with some of the elements of science and literature, so as to show parents how these may be taught without wearying the pupil's attention. Edgeworth was one of the first, after Dr. Watts and Mrs. Barbauld, to write books for children. His friend, Thomas Day, began his story, *Sandford and Merton*, as a contribution to Edgeworth's *Harry and Lucy*. The latter was subsequently published as part of his daughter Maria Edgeworth's *Early Lessons*.

In 1798, in conjunction with his daughter Maria, he published *Practical Education*, essays in which the influence of Rousseau's *Émile* is clearly shown. In 1802 Edgeworth published *Essays on Professional Training* (the first chapter of which gives his views as to the classification and curriculum of schools); and in 1816, *Readings in Poetry*. He also prepared with great labor a small tract called *The Rational Primer*, illustrating his method of teaching to read, which was based on the principle of always giving a distinct mark for each different sound of the vowels, and also showing by marks of obliteration which letters are to be omitted in pronouncing words. The educational works which he published in conjunction with his daughter had great influence upon school practice in England, and bore fruit in the work of Thomas Wright Hill (*q.v.*) and his sons in their school at Birmingham. Edgeworth was himself much influenced by the study of French writers on education. But he adopted no suggestions

inconsiderately or without practical tests in his own family circle. He was one of the first to realize that educational theories must be founded upon child study and himself to form a careful register of facts relative to his children's mental growth. He held that early instruction should be chiefly oral and experimental. In the last twenty years of his life, additional experience changed some of his former opinions in education, and confirmed others. He was strengthened in his belief that "many of the great differences of intellect which appear in men depend more upon the early cultivating of the habit of attention than upon any disparity between the powers of one individual and another," though he latterly allowed that there was more difference than he had formerly admitted between the natural powers of different persons. In early life Edgeworth, shocked by the long lessons imposed upon young children and by the mental fatigue and disgust thus induced in them, did not pay sufficient attention to systematic grounding in elementary subjects. In later life, however, he was led to believe that some drudgery of mind was not only useful, but necessary for children, in order to train them to habits of application. He thought that girls should be privately educated at home; for boys he preferred school training, except in an uncommon coincidence of circumstances. In his earliest attempts at education (writes his daughter), Edgeworth had endeavored to reduce to practice Rousseau's theories. "Finding the bad effects which resulted from following the system, from trusting too much to nature, liberty, free-will and the pupil's experiments in morality, my father for some time afterward inclined to the extreme of caution. . . ." But Edgeworth's experience led him in later life to attach the greatest importance to the cultivation of right habit, under judiciously regulated freedom, as a necessary concomitant of the cultivation of the reasoning faculty as applied to conduct. Writing in 1812, he stated, on behalf of his daughter Maria and himself, that they were "convinced that religious obligation is indispensably necessary in the education of all descriptions of people, in every part of the world. . . . I consider religion, in the large sense of the word, to be the only certain bond of society."

His influence, combined with that of his daughter Maria, with whom he closely collaborated in thought and literary work, was strong in English and Irish education alike, both as regards methods of teaching in home and school, and as regards administrative plans of national education. In the improvement of methods of teaching, Edgeworth's practice reflected in the first instance enthusiastic acceptance of Rousseau's theories; then underwent the chill of reaction against them, and finally took the form of a judicious combination of Rousseau's realism and boldness with the moral discipline of the older educational tradition. Not less

fruitful, though less immediately operative, was Edgeworth's influence upon the reorganization of the school system in England and Ireland. He was among the first to sympathize with the French ideal of a logically organized system of graded schools under state inspection, and no one was more successful in planting the seeds of this new administrative ideal in the reluctant soil of English statesmanship.

**EDINBURGH ACADEMY.**—See GRAMMAR SCHOOLS, ENGLISH; COLLEGES, ENGLISH; PUBLIC SCHOOLS.

**EDINBURGH HIGH SCHOOL.**—See GRAMMAR SCHOOLS, ENGLISH; COLLEGES, ENGLISH; HIGH SCHOOL; PUBLIC SCHOOLS.

**EDINBURGH, THE UNIVERSITY OF.**—Originally styled the College of Edinburgh, or The Town's College, was founded in 1583 by the Town Council of Edinburgh under general powers granted by the charter of King James VI, dated Apr. 14, 1582. From the first, the college possessed the privilege of granting degrees. In 1621 an act was passed by the Scots parliament which ratified to the college all the rights, immunities, and privileges enjoyed by other universities in the kingdom. This ratification was renewed at the union of the parliaments of England and Scotland in 1707. In the course of time, the college became known as the college of James VI, and later its designation changed, and the institution came to be called The University of Edinburgh; but it remained under the complete control and patronage of the town council until 1858, when by the Universities Act (1858) all the universities of Scotland received new and autonomous constitutions. From 1858 to 1890 the government of the university was vested in the *Senatus Academicus* (consisting of the principal and the professors), subject to the review and control of the University Court. The latter body is composed of representatives selected by postgraduates of the university, by present students, by the Town Council of the city, and by the *Senatus Academicus*. By the Universities (Scotland) Act of 1889 the constitution of the University Court was enlarged in numbers upon the already existing basis, and it was constituted a body corporate to which the whole property belonging to the university at the passing of the act was transferred with full powers of administration. The *Senatus Academicus*, as heretofore, regulates the teaching and discipline

of the university, subject to the review and control of the University Court. The present constitution of the latter body is as follows: four members elected by the General Council of the University, which is composed of all graduates, four members elected by the *Senatus Academicus*; the Rector's Assessor, the Chancellor's Assessor, the assessor elected by the Town Council, the Principal of the University, and the Lord Provost of the City are *ex officio* members of the body.

The university buildings at present consist of (1) the College or University (old) Building situated on the site of "Kirk of Field," the scene of the murder of Lord Darnley. The foundation of the building was laid in 1797 on a plan drawn up by the famous architect, Robert Adam, but for various reasons, was not completed until 1828. In this building are housed, at present, the library and reading rooms of the university, the classrooms of the faculties of Arts, Divinity, and Law, and part of the work of the Faculty of Science. Here also are the Senate Hall and the various offices for carrying on the administrative work of the university. (2) The university (new) buildings, begun in 1878 and finally completed in 1888, at a cost of over a quarter of a million pounds. Here are now housed the lecture rooms and laboratories of the Faculty of Medicine. (3) The University Hall, situated adjacent to the new university and erected in 1897 through the munificence of Mr. William McEwan, a citizen of Edinburgh. The hall is used for graduation ceremonies and other university functions. (4) The Reid Hall of Music, erected in 1859, is also situated near the new buildings, and here is conducted the work of the Faculty of Music. (5) The Usher Hall of Public Health, situated in the south of Edinburgh, was given by Sir John Usher, Bart., on the institution of a Chair of Public Health in 1898, and completed in 1902. (6) New engineering and physical laboratories placed on a site at a short distance from the old buildings have recently been erected (1905-1907) in view of the modern demand for practical work in the teaching of these subjects.

**The Inner Organization of the University.**—Up to 1858 the education provided by the University of Edinburgh followed mainly the traditional lines laid down at its establishment. At that time the fortunes of the university had fallen to a low ebb. Graduation in arts had almost ceased, and degree courses in law and divinity did not then exist. By the act of 1858 a commission was appointed to remedy this state of matters. In due course they established a preliminary examination for entrance upon a medical course, and laid down regulations for degrees in medicine. Thus, there were established the three degrees of Bachelor of Medicine (M.B.), of Bachelor of Surgery (C.M.), and Doctor of Medicine (M.D.). For the doctor's degree the requirements were a lapse of two years after the possession of the lower

degrees, and proof of having undergone a satisfactory course of general education in the Faculty of Arts. Under these regulations the number of students rapidly increased. The Commissioners next proceeded to frame regulations for degrees in arts, and as a result of their labors they established a one-degree course in this faculty. The subjects covered by this degree course were: Latin, Greek, mathematics, natural philosophy, logic, moral philosophy, and rhetoric (including English literature). At the same time they instituted honors degrees in classics; in mathematics and natural philosophy; in mental philosophy; and in natural science (including geology, zoology, and chemistry). The Commissioners next gave their attention to graduation in law, and in 1862 they laid down regulations for the degree of Bachelor of Laws (LL.B.), which was to be open only to those who had previously graduated in arts. This course, however, did not appeal to the public, for during the nine years after its institution (1862-1872) only twenty-four students were awarded the degree. Accordingly an agitation arose, which in 1874 resulted in the establishment of another and lower degree in law (B.L.) which could be taken by a student who had not previously graduated in arts. In 1864 the *Senatus Academicus* established a degree in the Faculty of Divinity, and also degrees in science in the departments of: (1) the mathematical science, (2) the physical sciences, (3) the natural sciences, and (4) engineering. It is to be noted, however, that at this time no separate faculty of science existed.

The next great change in the inner organization of the university took place in 1892. It was then enacted (1) that a preliminary or entrance examination should be incumbent upon all students entering upon a degree course in any existing faculty, and that the subjects of this examination should be English, Latin or Greek, mathematics, and one of the following, *viz.* French, German, Italian, or dynamics. This entrance examination was made common to all the four Scottish universities, and a joint board was established to control and regulate the examination. (2) In the second place, the universities of Scotland were thrown open to women students, and in Edinburgh women can now graduate in arts, in science, in medicine, in law, and in music. (3) The old seven-subject degree in arts had been found unsuitable in many cases, and moreover the exclusion of such subjects as history, political economy, and education from the arts course was regarded as an injustice. Accordingly, it was enacted that a student proceeding to graduation in arts must attend full courses in seven subjects, of which four must be (a) Latin or Greek, (b) English or a modern language or history, (c) logic or moral philosophy, (d) mathematics or natural philosophy. The remaining three courses were left to the choice of the student, subject to the condition that the group of seven

subjects must include either (a) both Latin and Greek, or (b) both logic and moral philosophy, or (c) any two of mathematics, natural philosophy, and chemistry. In addition the subjects in which an honors degree could be already taken were extended so as to include such courses as modern languages and history. These regulations were made common to the four universities of Scotland. The other important change made was the establishment of a separate Faculty of Science. As a result of these innovations, the number of students in attendance at the university for a time gradually decreased, until the schools were enabled to raise their standard of scholarship to the new entrance test. Lectureships in French, German, geography, and other subjects were gradually established.

In 1908-1909 further changes were made in the arts course, with the view of widening the degree courses in this faculty. By ordinance, passed in 1909, it is laid down "that the curriculum for the ordinary degree in arts shall consist of *five* subjects of which two subjects shall be studied for two academical years, provided that it shall be in the power of the *Senatus* with the approval of the University Court to reckon courses in two cognate subjects as two courses in one subject." The effect of this new regulation is to give entire freedom to the university in the framing of courses of study in arts. In Edinburgh, the subjects in arts are grouped under four departments, *viz.*: The departments of (1) language and literature; (2) mental philosophy; (3) science; (4) history and law; and the only general regulation laid down for the construction of a degree course in arts is that subject to the approval of an official adviser appointed by the University Court, "every curriculum for the ordinary degree must embrace subjects taken from at least three out of the four departments of study enumerated above." The Faculty of Science has, as we have already noted, been an independent faculty only since 1893. In addition to the courses leading to a degree in pure science, degree courses are now also provided in the following departments of applied science, *viz.* (a) engineering; (b) agriculture; (c) public health; (d) forestry. The Faculty of Medicine, in addition to the degrees mentioned, now grants on conditions similar to the doctorate in medicine a master's degree in surgery (Ch.M.). In 1894 the Faculty of Music was established, and provides courses for students desirous of obtaining the degree of Bachelor of Music (Mus. Bac). Higher degrees are conferred on graduates on presentation and approval of a thesis in the faculties of Medicine, Science, Arts, and Music. Honorary degrees in divinity and in law may also be conferred. The total number of matriculated students in attendance during the year 1908-1909 was 3321, made up as follows: medicine, 1475 (including 35 women students); arts, 1157; science, 300; law, 305; divinity, 64; music, 20. Within recent years, the University

of Edinburgh, in common with the other Scottish universities, has largely benefited from the grants received from the Carnegie University Endowment Fund. A number of new lectureships have been recently instituted, until at the present the number of professors and lecturers, exclusive of assistants to professors, numbers over a hundred.

**EDUCATION.** — Speaking generically, education signifies the sum total of processes by means of which a community or social group, whether small or large, transmits its acquired power and aims with a view to securing its own continuous existence and growth. The necessity of education rests upon a few simple basic facts. These are the difference of level between the mature and the immature members of a society and the facts of birth and death. Since it is certain that all the mature members of a society will die, it is obvious that the conservation of a society depends upon rearing the newborn members in such a way that they will appropriate its functions and sustain its values. We may imagine a community in which the difference in grade of power and achievement between the immature and the mature is so slight that it will be bridged over in the course of the natural growth of the immature; such is the case, for example, with many of the lower animals. But in human societies, precisely the opposite is the case; the mere physical processes of growth, if not intentionally given a certain direction, do not secure the maintenance of the current habits and ideals of a social group. Failure to direct the natural processes would surely effect the extinction of all that is characteristic of the society. In other words, since the important institutions and purposes of a society are not physically hereditary, they must be maintained through a social heredity; that is to say, by the deliberate direction given to the natural capacities of the newborn by the already existent social forces.

The more primitive, savage, or barbarous a community, the less the difference of level between the mature and the immature, and the less important, relatively, the function of education. Savagery and barbarism mean that there is a comparatively slight departure in the social institutions from the results that would naturally be obtained by physiological development apart from social control — slight, that is, as compared with what is termed civilization, though great absolutely. The relative simplicity and meagerness of social life mean that less is at stake socially, so that there is less need of special supervision of the process of growth

from infancy to maturity. Since every advance in the depth and richness of culture marks an increase in the difference of level between the mature and the immature, this constantly widening gap means increased necessity of education as the prime condition upon which the conservation of society itself depends.

This contrast leads us to our first fundamental distinction in education, that between formal and informal. In simpler social groups, the child becomes assimilated to the social activities and aims of his group by sharing, through play and work, in a constantly widening series of activities, in the life of those about him. He learns to do by doing, to share by sharing. Custom regulates the main details of life, and its rules are enforced in his conduct by imitation, suggestion, injunction, and prohibition with accompanying rewards and punishments. No *particular* social institution is required; the *school* does not exist as a specific institution of society. The child's natural associates are at the same time his sole teachers. At earlier and later puberty, however, there is something in the nature of more express instruction. There are in almost every tribal group special ceremonies of social commemoration and celebration; in connection with these, there are exercises for initiating the male members of the group into fuller social membership. Frequently these are quite complicated and last several weeks; they are so conducted as to impress upon the minds of the youths, under conditions of awe and intense vividness, the traditions and moral ideals of the group. There is also at an early period a certain amount of more specialized training for the calling of medicine man and priestcraft. As the arts of life, civil and military, became more complex, provision was made for them. The chief cause of the school as a formal institution was, however, the invention of letters. The symbols required special training for their mastery, while their existence permitted and encouraged the accumulation of knowledge far transcending the immediate environment, and hence not capable of acquisition through participating in the direct activities of the environment.

We are not, however, primarily concerned with the distinction between formal and informal education as a historic matter, but as a standing distinction of fundamental importance between out-of-school education and schooling. Children to-day, for example, get their initiation into and chief contacts with their mother tongue in their informal education; that is, they get it by partaking in certain forms of social life which exist on their own account, not for the sake of education. Other matters, technical science, algebra, and "dead" languages, are mainly relegated to formal education; many other topics lie partly in both fields. Many of the most important problems of educational theory and practice are determined by this situation. There are certain

obvious advantages in the type of education that depends upon securing the educative result not by subject matter and method selected and arranged for the express purpose of education, but by actual direct participation in some form of contemporary life valued and performed on its own account. Genuineness, vitality, depth of interest and of assimilation, and consequent assurance of influence upon habit and character, are features of the incidental type of education. In contrast with these marks, school education tends to become remote and artificial (abstract in the unfavorable sense sometimes given that term), devoted to modes of technical skill and accumulation of knowledge with only a minimum effect upon character, because its affairs are not organized into the ordinary practices of daily life. Consequently, it is a constant cry of the educational reformer of each age that the school education has got too far away from the actualities of life to be genuinely educative. On the other hand, informal education, however deep, is almost sure to be contracted, since the environment in which an individual can directly share is limited in space and time. Moreover, its incidental character is favorable to its being incidental in the bad sense, *viz.*, casual and fragmentary. Many times the type of activity in which children would naturally take a part by direct sharing is relatively, if not absolutely, an unworthy type; moreover, since family and local environments vary tremendously, excessive reliance upon informal education tends to the perpetuation of class and even caste differences.

These considerations define the problem of formal education. First, the selection, with attendant criticism and rejection, of the social types and subject matter best worth perpetuating. Secondly, the widening of the usual or current environment through supplementing it with the subject matter and aims with which children would hardly come in contact in their usual family and neighborhood environments. Thirdly, the more systematic arrangement of the social subject matter with a view to securing the most economical coordination of its constitutive portions. In other words, conscious or deliberate education has to provide an environment (*q.v.*) (*a*) idealized or purified, (*b*) universalized, and (*c*) systematized, in comparison with that under which informal education goes on. At the same time, pains must be taken to avoid isolation of motive and matter, and to take advantage of the superior vitality and more intimate connection characteristic of informal methods. Every generation, in a society that is changing, has, to some extent, to work out this problem anew. For the shiftings of social activities change the domestic, and the industrial environment, and hence tend to exclude some factors of educational value from the direct environment and to introduce others. This means that the school must take some account of what the home and neigh-

borhood are letting go, while they may correspondingly relax their attention to matters that are falling more within the scope of out-of-school experience. As the last two or three generations have seen an industrial revolution, which has already profoundly affected domestic and civic life, and as this has also been accompanied with a tremendous cheapening of literary or printed matter and a corresponding increase in its accessibility and ease of circulation, the problem of the proper adjustment of school and out-of-school education is at once more urgent and more serious at the present time than at any previous epoch.

I. A return to the original definition will now serve to bring out the essential phases of education; they are the social-ethical, the biological, and the psychological. The starting point and the aim are both clearly social. Societies, social groups, with their equipment, their traditions, their purposes, always exist, and are, so to speak, in possession of the field. They aim at their own perpetuation; they will not knowingly permit the introduction of anything destructive of their own most cherished aims; and they will insist upon ideals of subject matter and method that seem indispensable to their own continuity of being. We must not, however, be misled by the simplicity of the words, society and social group, into overlooking the very great complexity and diversity of the facts to which these words refer. Any modern state (the United States, perhaps, to a greater extent than any other) is a congeries of communities within communities, of social groups of differing religions, moral traditions, cultural equipments, economic differences, etc. In a modern complex democracy the burden of finding a common denominator amid these differences falls upon the public school system more than upon any other one agency: a fact of great significance in connection with the rapid development of a nationalized and secularized education in the last century. It may be doubted whether any scheme can be devised as well calculated for getting the benefit of the diversity of factors and at the same time avoiding the attendant dangers of centrifugal divisions as is the public, secular system of universal education. But in any case a glance below the surface will show that at all times social considerations have been the controlling considerations in educational systems, and this as regards not merely their institutional forms, but their subject matter and method of study as well.

The biological factor comes into full view as soon as we consider that the necessity of education is due to the existence of immature beings who are to be directed in their growth. The conservation of social values is to take place through individuals who are born helpless, but with certain structural capacities and with certain urgent or impulsive tendencies which manifest themselves in accordance with biological princi-

ples. In other words, education, from the side of the beings to be educated, is a matter of taking an animal being whose activities are primarily upon the biological plane and transforming them into functions that operate upon the social plane. Since the values to be transmitted have to be perpetuated through the medium of those whose activities are naturally upon a different plane, the problem of effective and economical education is identified with the problem of discovering the native, or biological, equipment which lends itself most easily and fruitfully to effecting the type of growth desired. Hence the constantly increasing attention in modern educational theory to the nature of infancy and its prolongation, to the biological study of instinct and impulse in the child, and to all the physiological problems of normal, retarded, and abnormal growth. Even details of brain anatomy and of school hygiene get a profound meaning when looked at from this point of view.

The psychological phase of education has to do with the biological factors functioning under conditions of social control for the realization of social ends. In other words, only social psychology is of primary importance for education. However it may be for other purposes, from the standpoint of the *educator's* interest and problem, "mind," "consciousness" denote the natural capacities of the individual as these become available for social uses and are saturated with social contents. Memory, for example, is a certain biological capacity of retentiveness, shaped with a view to creating socially available habits. Perception, from the educational point of view, is not a bare mental faculty face to face with a purely physical world; it is the capacities of eye, ear, touch, etc., trained to take account of the conditions that are of social importance, and to do so in accord with the values socially attached to those objects. The extreme individualism of much of modern pedagogy is itself a symptom of a certain social fact back of it. Only because modern society is democratic (that is, makes much of the notion of the freedom and relative equality of its members) are initiative, independence, freedom of action and thought, important as educational aims. Hence, at bottom, the psychological strain in modern educational theory and practice presupposes the context of a democratic society in which the individual is to live. The aim is not to understand individuality in the abstract, but to understand individuality with reference to forming and cultivating those traits of character by which the democratic social medium sets store.

II. So far we have considered education from the standpoint of its place and function in societies that make use of it to secure the conservation and expansion of their own ideals. We may, of course, also regard the process from the standpoint of the immature beings who at a given time are being transformed into social members, to sustain the

community type of life. So viewed, education may be defined as a process of the continuous reconstruction of experience with the purpose of widening and deepening its social content, while, at the same time, the individual gains control of the methods involved. (See *FORM AND CONTENT*.) That is to say, from the standpoint of the one educated, the beginning is at the biological end, not the social. Experience is crude, narrow, and largely self-centered. Yet it has within itself capacities of assimilating and re-creating what is most perfected, developed and generalized in culture, for otherwise the wonderful products of art, industry, and science would never have come into being as in the past. Hence the educative process is a constant process of making over the existing experience, so that the social values lying blindly and crudely within it shall be clarified and enlarged. Yet the leverage of this transformation must be sought and found within experience itself; experience cannot be made over from without, but only in the process of its own growth. There are dynamic, transitive tendencies in the very nature of experience which tend to keep it growing and expanding. The educational process provides stimuli that appeal to these intrinsic tendencies. That this making over involves not only an increase in the socialized contents of experience but of self-control is evident in the fact that the stimuli provided by the educator must not work to develop dependence upon foreign supports. On the contrary, while it is true that one can never dispense with stimuli to action and growth, yet a genuinely educative growth always puts it more in the power of the individual to search out the conditions needed for his own further growth. When he has attained this power, schooling ceases. In assimilating into his own experience social subject matter he must do it in such a way as also to master the tools and technique of social progress. So far as this happens, a balance is preserved between the social and the individual, or psychological, aspects of the education of the pupil. There are systems of education which succeed in saturating the pupils with social subject and with loyalty to social aims, but that afford little power of personal control in the reshaping of experience. There are others that yield excellent gymnastic training of isolated individual powers, but that furnish only a slight modicum of socially important content. (See *FORMAL DISCIPLINE*.) But according to our definition, in order to be genuinely educative both results should be simultaneously accomplished.

Historically considered, it is not surprising to find that classic Greek definitions of education emphasize the social aim and the social character of the subject matter, with some tendency to subordinate the individual or psychological side, or at least, to take individual capacity as a pretty definitely fixed thing; that the Renaissance definitions alter-

nate between emphatic assertions of individual claims and equally emphatic recognition of the claims of the new nationalities that were springing up amid the passing away of feudalism; that the typical eighteenth century is individualistic on one side and cosmopolitan on the other; while nineteenth-century conceptions at first perpetuated the notion of "harmonious and complete development of all the powers of the individual," and then reacted to social definitions conceived sometimes in a nationalistic spirit (patriotic citizenship), sometimes in terms of industrially efficient service, and sometimes in a somewhat broad and vague philanthropic spirit. At the present time, "social efficiency" is probably the favored phrase. Social efficiency may, however, be taken in a narrow and external way, or in a broader and more liberal sense. In the former, social efficiency is supposed to be measured on the basis of definite output of overt acts and external products, with little attention to their reaction into the individuals' appreciation of the meaning of these acts and commodities. To be doing something is set over against the enrichment of consciousness at the expense of the latter. In the truer and more generous sense, social efficiency means also increase of ability to share in the appreciation and enjoyment of all values of social intercourse, and thus necessarily includes the enriching of conscious experience.

From whichever side education be defined, whether from that of the community carrying it on or that of the individuals educated, it will be found to involve three factors, which may be distinguished but not separated. These are (a) the specific institutions which are differentiated for the special work of education; (b) the subject matter (see COURSE OF STUDY), and (c) the typical methods of discipline and instruction employed to realize the ends in view.

EDUCATION, ACADEMIC STUDY OF. —

In this article consideration is given only to the organized work in higher institutions of learning. The practical or professional consideration of the study of education is treated under the caption TEACHERS, TRAINING OF. Some attention is also given to the same aspect of the subject in the various articles on the national systems, especially that of Germany, under the subtitle Training of Teachers. The scope and method of the scientific study of education is more fully considered in the articles on EXPERIMENTAL PEDAGOGY; EXPERIMENTAL SCHOOLS; and RESEARCH IN EDUCATION. The content as well as the development of the special phases of the study of education is given under the titles, HISTORY OF EDUCATION; PHILOSOPHY OF EDUCATION; PSYCHOLOGY, EDUCATIONAL, etc.

ENGLAND. — The opportunities for the study of education in England are of comparatively recent origin. In the field of secondary education tradition, a narrow curriculum, reliance on experience rather than training, the confidence placed in the teaching ability of the scholar as such, were some of the factors which militated against professional studies; while in elementary school work the apprenticeship system prevailed until a few years ago. In 1825 there appeared a *Plan for carrying into effect the Objects of the Society for Promoting the Science of Education*, by Mr. Davenport, but little more was heard of the project. From 1837 to 1839 existed the Central Society, which aimed at "ascertaining the objects of education and determining the means of attaining them . . . and to give the theory of education a more scientific character than it has yet assumed."

In 1848 a series of public lectures on education was organized to propound the views of the Congregational Board of Education, which favored voluntary effort in education as opposed to government intervention (see *Crosby Hall Lectures on Education*, London, 1848). Probably the earliest attempt to promote the study of education among teachers was made by the College of Preceptors, established in 1846 and empowered by its charter to "institute lectureships on any subject connected with the Theory and Practice of Education." In 1861 began the series of monthly meetings in London, at which prominent scholars and teachers delivered lectures on educational topics, but unfortunately the audiences only numbered from two to sixteen members. The first examination in the theory and practice of education was held in 1867, and twenty-four candidates passed. In 1873 the College established a professorship of the science and art of education, the first of its kind in England, followed in 1876 by the establishment of the Bell Professorships of Education at the Universities of Edinburgh and St. Andrews. Regular courses of lectures have been given since that time, and a special course is given in January at the winter meeting of the College. In 1895-1898 a training department for secondary teachers was conducted. In his *Report to the Schools Inquiry Commission on Schools in the West Riding of Yorkshire* (1868), Fitch strongly recommended the establishment of a professorship of pedagogy in one of the universities, and of degrees in education. The Headmasters' Conference in 1872 and subsequently also urged the universities to remedy the defect and provide for the study of education. Considerable pioneer work for the promotion of the study of education was done by C. H. Lake, Joseph Payne, Thomas Hall, Robert H. Quick, Joshua Fitch, and others. The Education Society, or the Society for the Development of the Science of Education, was founded in 1875 with an ambitious program, which, since it may well be adopted at the present period, is here given in full: to collect and classify educational facts; to discuss educational problems on a definite plan, and to arrange and record facts; to give lessons and discuss the principles involved; to examine and report on educational machinery; to get acquainted with educational ideas abroad; to examine and criticize the labors of eminent educationists; to examine the lives of eminent men; to consider the educational influences (conscious or unconscious) affecting their careers and to investigate the educational forces at work; to publish proceedings. Papers were read and lessons were given and criticized, but the influence of the Society among the rank and file of teachers was not great. In 1887 the Society was merged with the Teachers' Guild. From 1878 there has been a gradual increase in the number of training colleges for teachers, beginning with the establishment in

that year of the Maria Grey Training College in London, for women; in 1879 the Teachers' Training Syndicate was appointed at Cambridge to organize courses in the theory and practice of education, and in the same year R. H. Quick was appointed to deliver a series of lectures on education at that university. In 1883 a teachers' diploma examination was instituted by the University of London. In 1890 the establishment of day training colleges in connection with the universities paved the way to some extent for the recognition of education as a university study. The opportunities for professional study were rapidly increased after 1894, when the special preparation of secondary teachers was recommended by the Bryce Commission, and became the logical outcome of the proposals for a teachers' register and the Education Act of 1902, which placed secondary education under the control of the central board. Courses in education both for elementary and secondary teachers are now found in most of the universities under the charge of a professor of education. There seems some indecision at present as to the faculty under which such courses should be placed, since both science and art students may take education toward their degrees. In the universities of Manchester, Liverpool, and Sheffield, for example, the instructors in education belong to both the faculties of arts and science; in the Scottish universities education is part of the faculty of philosophy. In no case, however, is there a separate faculty of education, nor is there any provision for degrees in education or pedagogy. A chair in this subject does not exist as yet at Oxford, where a reader is at the head of the work, or at Cambridge, where there is a lecturer. Students who prepare for teaching in secondary schools take the study of education as postgraduate courses. A few summer courses in education are offered, those at St. Andrews University and Oxford being the most prominent. The requirements for diplomas and certificates in education, which will give the best indication of the scope of educational study, include some or all of the following subjects: history of education; psychology, logic, and ethics; observation of children, and child study; school hygiene; principles of education; principles of teaching; school organization, discipline, and management; method. As a general rule most of the courses here given are accessible to students in day training colleges giving preparation for elementary schools.

The following courses may be taken as representative:—

MANCHESTER UNIVERSITY.—*The Mental and Physical Life of School Children*.—The course will consist (a) of lectures offering an elementary introduction to genetic psychology, combined with (b) observation of children and other practical exercises in schools. In the Lent term, School Hygiene (five or six lectures).

*Scientific Principles of Teaching.*—(1) The curriculum, especially with reference to the elementary school. (2) General principles of method, including the study of lesson notes. (3) Special method in the pursuit of individual branches of the curriculum. *Systematic Review of the Principles of Education*, including a study of the corporate life of schools and of school management. Michaelmas term. Selections from the History of Education. Lent term, *The Observation of Children and School Hygiene*; demonstrations, practical work, and lectures. *The Pursuits of the Infant School*. Observation, lectures, and demonstrations. *Selections from the History of Education*, bearing especially on the teaching of young children. *Lectures*, with demonstrations, on the organization and management of secondary schools, on periods in the History of Education, and on educational statistics.

**SHEFFIELD UNIVERSITY.**—I. *History of Education*: (a) the educational reformers of the eighteenth century, with special study of Rousseau's *Émile*; (b) English education during the nineteenth century. II. *Theory of Education*: (a) the meaning of education; (b) the aim of education as determined by the consideration of (1) personality, (2) society; (c) the process of education as determined by (1) mental development, (2) the need of equipment for practical life, (3) the value of the subjects taught, (4) the organization of schools and classes. III. *The Practice of Education*: (a) the general principles underlying method in teaching; (b) the methods of teaching particular subjects, with special reference to those which students are going to teach; (c) organization; (d) school hygiene.

Advanced study of education in England is only in its initial stages. Up to the recent years Germany was still the Mecca of the educationalist, but there are signs of a growing activity at home, particularly along the lines of relating the results of experimental psychology with education. But unfortunately a good deal of the work in this field is done privately, in the sense that no university funds are placed at the disposal of the students. In London the University College offers facilities for research along psychological lines. The department of education in the University of Sheffield is provided with a small psychological laboratory, which is maintained by the university authorities. At Edinburgh University, students in training must take a term's work in the psychological laboratory, and the new training college is to contain a laboratory. The Teachers' Guild has formed a research committee which receives and discusses abstracts from psychological journals and assists in the prosecuting of research in the schools. But a good deal of the work of this type which is gradually finding its way into most universities is individual and unorganized, and there is some danger of duplicating not only English experiments, but a considerable amount of the

work already done elsewhere. The question of educational research formed the subject of a report in Section L of the British Association at its 1910 meeting, in which the committee not only pointed out the need of funds for the furtherance of educational research, but referred to the progress made by other countries as compared with England. The *Training College Record* has recently begun to devote space to experimental pedagogy and is now published as the *Journal of Experimental Psychology and Training College Record*.

In addition to the means for study already referred to, the work of associations, such as the Child Study Association, should be mentioned. Several good pedagogical libraries are accessible to students in London at the Board of Education, at the Teachers' Guild, and at the College of Preceptors.

**SCOTLAND.**—Professor James Pillans, Professor of Humanity in the University of Edinburgh, and author of *Lectures on the Proper Objects and Methods of Education*, had urged the establishment of chairs in education in at least two of the Scottish universities in 1828, and was so encouraged at the reception of the proposal as to repeat it in 1834 and suggest chairs in each of the four universities. At its preliminary meeting in 1847, the Educational Institute of Scotland, a body composed of members interested in education, recommended a wider dissemination of the theory and practice of education, and like the similar body in England, the College of Preceptors, arranged for a course of lectures in Edinburgh in 1847-1848. In 1851 the Institute produced a scheme for lectures in the theory and practice of education, but was without funds to put it into operation, but the organization constantly pressed for the establishment of professorships in education, and sent a memorial to the university commissioners in 1859. The appearance of a strong article on the subject in 1862 in the *Museum* encouraged Professor Pillans once more to put forward his scheme and to that end he interviewed Mr. Lowe, vice-president of the Education Department, on the subject, only to be told that there was "no science of education." From 1873 onward the matter was taken up in the press, e.g. *Fortnightly Review*, *The Schoolmaster*, *Scotsman*, *Courant*, *Daily Review*, *Glasgow Herald*. In 1876 the Bell Chairs of Education were established in the Universities of Edinburgh and St. Andrews, but for a long time the academic recognition of the subject was slight. Lectureships in education were established much later at Aberdeen (1893), and at Glasgow (1894). No degree is conferred in education, but the subject is accepted as a qualifying subject for the M.A. degree.

**FRANCE.**—The first public course of education in a university faculty was established at the Sorbonne in 1883 for M. H. Marion (*q.v.*), a "lay Fénelon," whose views have profoundly changed the educational traditions of France.

He occupied the chair until his death in 1896. He directed practical conferences at which the students discussed the best methods of education (see *Revue Internationale de l'Enseignement*, 1883 and 1896). This first organization served as the prototype for present practice. In 1884 educational conferences were organized at Lyons by M. R. Thamin, now Rector of the University of Bordeaux. Some irregular attempts to introduce the study of education were also made at Bordeaux by M. Espinos in 1882. At Toulouse M. Compayré lectured in 1875 on the history of education and on child psychology in 1879.

At present regular conferences or a course in education exist in all the universities, in which students prepare for one of the *agrégations* in secondary education. (See FRANCE, EDUCATION IN.) Since 1906 all candidates for different *agrégations* must study pedagogy at the same time as they are pursuing the courses for their *agrégation*. In the first year they take a theoretical course, given at Paris by M. Durkheim, at Lyons by M. Chabot, at Bordeaux by M. Richard, at Montpellier by M. Foucault, at Grenoble by M. Dumesnil, etc. Such courses deal generally with the history and theory of secondary education, the psychology of the pupils, the evolution of the intellectual faculties of the child, the rights of children, social pedagogy, etc. These theoretical courses are nearly everywhere accompanied by other conferences conducted by specialists on school hygiene, training of the memory or attention, etc., defects of vision or hearing among pupils. The first part of the pedagogical course is intended to give general principles. In the succeeding year the candidates for the *agrégation* attend courses on special methods, and, before entering on their preparatory stage at a lycée, must attend a series of conferences on the best methods of instruction in the subject in which they expect to attain their *agrégation*. At Paris the rector, M. Liard, who was the first to organize this course, holds the opening conference in person, while the rest are given by the most qualified professors, e.g. M. Croiset in letters, M. Luvissé in history, etc. They deal with the teaching of literature, grammar, philosophy, history, geography, modern languages, mathematics, natural and physical sciences. These courses and conferences are at times attended not only by the candidates for the *agrégation*, but, as at Lyons, Grenoble, Montpellier, etc., by professors, teachers, and mistresses in the boys' and girls' lycées, whenever possible. A diploma is given at Lyons to those students who produce an interesting and original work on the subject matter of the courses. (See FRANCE, EDUCATION IN; TEACHERS, TRAINING OF.) J. P.

**GERMANY.** — The first attempt to give a professional education to teachers of the higher schools is due to J. M. Gesner (*q.v.*), who founded (1734) a *Seminarium Philologicum* at

the University of Göttingen, in which candidates of theology were prepared for their work as school teachers. Their pedagogical study was based on Gesner's *Institutiones rei scholasticæ*, an exposition of the principles of Ratke, Comenius, and Locke, and was supplemented by practice lessons in the Göttingen schools. A considerable impetus was given to the study of education in several of the Prussian universities through the efforts of Zedlitz (*q.v.*), the minister of Frederick II. He, being an admirer of Basedow and his Philanthropinum in Dessau, called the philanthropist, E. C. Trapp (*q.v.*), to the University of Halle as professor of pedagogy and director of the pedagogical seminary (1779). Trapp's work in Halle was a failure, and he was succeeded (1782) by Fr. A. Wolf, under whom pedagogy was soon entirely supplanted by philology.

At the University of Königsberg, Zedlitz arranged to have the professors of the philosophical faculty take turns in lecturing on pedagogy (1774). In this way Kant (*q.v.*) gave four courses on pedagogy the first time in 1776, taking as a basis Basedow's *Method-book*, for which he later on substituted Boek's *Lehrbuch der Erziehungskunst* (Königsberg, 1780).

In a few other universities lectures on pedagogy were delivered and pedagogical seminaries founded, as in Helmstedt, Heidelberg, and Kiel. The pedagogical Seminar at Heidelberg was conducted by F. H. C. Schwarz, the historian of Education. His announcement published in 1807 (*Einrichtung des Pädagogischen Seminariums auf der Universität zu Heidelberg*) sets forth a very modern course for the two years, including pedagogy, didactics, catechisation and method for schools and other educational institutions, and history of educational institutions and literature. The students wrote essays on assigned topics, gave accounts of their own experiences and observations at school visits, and acquired some practical experience. The real introduction of pedagogy as a university study is due to the activity of Herbart (*q.v.*), Kant's successor in Königsberg. The pedagogical seminary, which he established in 1810 and directed until he left Königsberg in 1833, became the model of other important institutions of this kind. In 1843-1845 Gustav Thanlow, a disciple of Hegel, conducted a pedagogical seminar and lectured on the philosophy of education at the University of Kiel. (See his *Nothwendigkeit und Bedeutung eines pädagogischen Seminars auf Universitäten; und Erhebung der Pädagogik zur philosophischen Wissenschaft oder Einleitung in die Philosophie der Pädagogik*, Berlin, 1840.) Brzoska, one of Herbart's pupils, carried the idea of a pedagogical seminary to Jena, where, after his early death, it was put into execution by K. V. Stoy (*q.v.*), and afterwards (from 1885 on) by William Rein, who still holds the professorship of pedagogy and directs the pedagogical seminary and the practice school connected with it. In like manner, another follower of Herbart, T. Ziller

(*q.v.*), worked in Leipzig, where (in 1862) he established a pedagogical seminary which he directed until his death (1882). The work of Strümpell in Leipzig is confined to theoretical pedagogy, while that of other professors, such as Hofman in the same university, of Ziegler in Strassburg, Uhlig in Heidelberg, Schiller in Giessen, extends also to observation and practice teaching.

On the whole it may be said that the great interest in the study of education, and the care for the professional training of the teachers of the higher schools, which was very prominent towards the end of the eighteenth century, later on in the universities gave place to a certain contempt of pedagogy. It was assumed that, if the teacher was a thoroughly trained scholar in his specialty, be it philology or science or mathematics, the ability of imparting his knowledge to young minds would follow of itself. More recently, however, the importance of a theoretical and practical training in the science and art of education is becoming more and more recognized.

As organized at present, the academic study of education is incorporated for the most part into the work of the *Seminarjahr*, which is required of all prospective teachers in secondary schools, and is organized under the direction of selected secondary school directors. And in addition to this the traditional seminar work of the university for the year preceding the *Seminarjahr* has been directed largely to the academic training of these prospective teachers. The work in direct connection with the universities is largely theoretic and has been becoming gradually of less and less importance, while on the other hand the term *Seminar* is being applied now almost wholly to this practical work of the *Seminarjahr* under the control of the directors of important secondary schools. At the present time there are about seventy such designated schools in Prussia, each being responsible for eight or ten students per year. The work of these seminars, which is based upon a thorough mastery of the appropriate subject matter, consists in a study of the theory and practice of education in relation to the higher schools under the supervision of the school directors, together with practical observation in one of the higher schools, to which they are assigned in groups of eight or ten. Here twice a week discussions occur upon all sorts of theoretical and practical questions which arise out of the work of the school. Such discussions necessitate investigation and study of the kind which formerly in Germany and elsewhere now would usually be organized into university courses of instruction. This work is fully described in the article GERMANY, EDUCATION IN, in the section on Training of Teachers. (See also TEACHERS, TRAINING OF.)

For this reason the formal study of education in the universities as an independent academic subject has little place. There is

only one special professorship in education at the present time, and only recently the Bavarian authorities refused to sanction the establishment of special chairs in education. However, some courses on the subject are usually offered in most universities. Ample provisions are made for the study of psychology, pure and experimental, of philosophy, logic, and ethics. Such courses in pedagogy and history of education as are found are given by the professors or docents in the faculty of philosophy. The fullest courses in these subjects are found at Leipzig, where the preparation is given for teachers in the higher schools of Saxony. These include history of education, modern educational problems, introduction to theory and principles of education with practical work, physical education, and method. Only one university, Jena, has a recognized practice school. At Leipzig use is made of the local higher schools for practical work and observation. Göttingen and Kiel also announce pedagogical seminars, but for the present they are in abeyance. But the facilities at the universities are inadequate, for the reason that the professional preparation of teachers is not part of the work of these institutions. Advanced study of education is stimulated in lower schools, at any rate, by the necessity of meeting the standards of promotional examinations. For the special training of normal school teachers and some administrative officials a special course (*wissenschaftliche Fortbildungskurse*) has been established in Berlin, including educational subjects. Much professional activity is shown by teachers' associations and in individual study and experimentation. At Leipzig the Teachers' Association established an important institute for experimental pedagogy and psychology (*Institut für experimentelle Pädagogik und Psychologie*), and in Munich a plan for a similar institute (*pädagogisch-psychologische Institut*) was drawn up in March, 1910. School museums and good educational libraries, especially in Berlin and Leipzig, offer excellent opportunities for research.

In the following table a list is given of the courses announced in the German universities for the winter semester 1910-1911. Only those courses which are specifically educational are mentioned, without any reference to courses in ethics, philosophy, and pure psychology, which are found in all the universities.

EDUCATIONAL COURSES IN GERMAN UNIVERSITIES

Winter Semester 1910-1911

(Figures in brackets denote number of hours per week)

Berlin.

- Diseases of School Children. (1)
- Teaching of Modern Languages. (2)
- Principles of Secondary Education. (1)
- Experimental Pedagogy. (2)
- Experiments in the Psychological Institute. (3)
- Conference on Recent Research in Experimental Psychology. (2)

- Bonn.

**UNITED STATES.** — Although the opportunities and facilities for the scientific study of education are far better and more complete in this country than in Europe, their history does not go further back than a quarter of a century. Indeed, it may be said that a proper conception of what the study of education should stand for has only been formed within the last few years. Remarkable provision was, however, shown by the faculty of Amherst College as early as 1826. Their report presented on Aug. 21, 1826, to the board of trustees, in which they recommended the introduction of a system of electives, contained these significant

proposals: "But whatever may be thought of these suggestions, there is one new department of great practical importance which it appears to us should be annexed to the college, as soon as the funds will anyhow permit — we mean the *Science of education*. When it is considered how this lies at the very foundation of all improvement . . . it is truly wonderful to us that so little attention has been bestowed upon the science of mental culture, and that there is not . . . and never has been, a single professor of education on this side of the Atlantic." A new system of "equivalents" was introduced in 1827, but the science of education formed no part of them.

Important work was done for a period extending over nearly twenty years (1823) by Rev. Samuel R. Hall, the founder of the first normal school in the United States, at Concord, Vt. (1723-1830). In 1830 he removed to Andover, and there opened a teachers' seminary to educate teachers and others. While only the common branches of school education were given, there was a special course in the art of teaching; in 1835 there was a professor in natural science and the art of teaching, and the course of study was announced to be more professional. In 1837 Hall moved to Plymouth, N.H., where he also opened a teachers' seminary and himself gave fifty lectures on the art of teaching each year. When he moved to Craftsbury, Vt., in 1840, he added a teachers' department, which he conducted up to 1846. Hall was the author of the *Instructors' Manual and Lectures on Schoolkeeping* (Boston, 1829), which, according to the *Annals of Education* stood alone as a book on principles of education amidst the ever increasing number of school textbooks. In 1831 a professorship of education was established at Washington College in western Pennsylvania, according to a record in the *Annals of Education*, Feb. 1831, p. 82. In 1838 weekly lectures were given before the Massachusetts Board of Education, among others, by Horace Mann, James G. Carter, and Rev. Charles Brooks. But generally the demand of this period, which may be followed in the volumes of the *Annals of Education*, was for the provision of professional training of common school teachers rather than for higher study of education. (For further details see TEACHERS, TRAINING OF.) In most cases the colleges and universities were compelled by the demand of their students and the insistence of those who recognized the inefficiency of secondary school teachers to provide some means of acquiring a slight professional training before their entrance into the secondary schools. It was obvious that a large number of college graduates had devoted themselves to the teaching profession, and that the number of these would necessarily increase with the multiplication of high schools. The slow progress made at the beginning was due, as in England, to a feeling that education did not offer a field of study, that experience was the

best type of professional training, that, if such work had to be done, the normal school, and not the college or the university, was the place for it. But in spite of contempt and ridicule, lack of encouragement and inadequate equipment, education, at first assigned a subordinate position in a faculty of philosophy, was gradually provided with a professor, became established in a department, and later in a college with separate buildings, faculty, and administration.

With the opening of New York University (then called University of the City of New York) in 1832 there was established a chair of the philosophy of education for "educating teachers of common schools." Thomas H. Gallaudet (*q.v.*) filled the post during the collegiate years 1832 to 1831. This was probably the first effort made in the United States for the special preparation of teachers of common schools, and certainly the first of such work in college. In his *Seventh Annual Report* (1842-1843) Horace Mann urged the necessity of the proper preparation of teachers. "Why," he asked, "should we require a lawyer or physician to study his profession, and let the teacher . . . go unacquainted with his business?" When called to the presidency of Antioch College in 1853, he introduced a course in education. In 1850 the recommendations of President Wayland (*q.v.*) of Brown University for a course of instruction in the science of teaching was accepted, and S. S. Greene of Boston became the first professor of didactics at this university; but the chair was abolished in 1854 owing to lack of funds. The students who desired the subjects connected with it were advised to go to the Rhode Island Normal School at Providence. An abortive attempt was made to introduce the study of education in Missouri University in 1877. At the State University of Iowa a chair of Mental Philosophy, Moral Philosophy and Didactics was established in 1873, when the provision of instruction in education had been advocated for thirteen years (from 1853). Sporadic attempts to provide facilities for college courses in education were made throughout this period. Thus B. A. Hinsdale lectured on teaching at Hiram College each fall term from 1870 to 1882, continuing a custom introduced in President Garfield's time in 1856. At Michigan University the Superintendent of Public Instruction, Dr. John M. Gregory, voluntarily offered his services in 1860 to give courses in the principles and philosophy of education, organization, management, and instruction of schools. He gave two lectures a week, which were attended not only by the college seniors, but also by members of the law and medical schools. But in 1879 a chair devoted to the professional training of teachers was established at this university by President James B. Angell, who had been at Brown University under President Wayland. W. H.

Payne was the first professor of the Science and Art of Teaching. At Columbia University President F. A. P. Barnard strongly advocated the professional education of teachers in the annual reports of 1881 and 1882, and it seems highly probable from his correspondence with Henry Barnard that an unsuccessful attempt was made at this time to secure the services of Professor S. S. Laurie of Edinburgh. This proposal led to the establishment at this university of a course in philosophy of education, which was later to be merged in Teachers College. Since that period chairs, schools, departments, and colleges devoted to the study of education have been established in most of the larger colleges and universities, and few of the smaller colleges have failed to provide some courses in education, however inadequate these may be.

Within the last ten years there has been a rapid increase in the provision of chairs of education and in the establishment of schools and departments of education or in the separation of these out of other departments. Thus in 1901 the University of West Virginia founded a department of education; in 1902 Missouri University obtained a teachers' college; in 1905 the University of Virginia established a school of education; similar establishments followed in other institutions. At present many, if not most, of the institutions bearing the title of college give courses in education, in many cases no better than, and in some cases inferior to work in normal schools. But in the better institutions the education departments not only meet the demand for trained teachers in high schools, but provide opportunities for research based on scientific methods. Further, a new aim is beginning to make itself felt, and its realization in many instances is a remarkable testimony to the progress of a subject which so recently was pushed into the background almost universally. The study of education is no longer confined to the professional needs of the teacher, but is thrown open for its cultural value and importance in civic life of the future citizen in all walks and professions of life. While in the early stages of its development education was given no academic credit, it is now everywhere recognized as a proper study in the junior and senior years. The historical sketch given above illustrates how education has gradually become independent of other departments. This not only adds new dignity to the subject, but permits it to develop along lines appropriate to it. With this goes the question of organization. As was indicated in the historical sketch, the study of education began as an appanage of one of the older chairs, and it has gradually developed to such dimensions that a separate organization was found necessary for it. In many instances, especially in the smaller colleges, the courses in education continue to be given in the department of liberal arts and sciences; at Michigan University education forms part of the department of

literature, science, and arts. While it is true that some parts in the study of education touch the academic departments very closely, the general feeling is that this subject should be organized in separate departments in colleges and in separate schools or colleges in the universities, while liberal arrangements can easily be made for intimate relations between related branches.

Considerable advance has been made on the period when the study of education, under the title of didactics or pedagogy, could be dispensed in one or two books, like David P. Page's *Theory and Practice of Teaching* (New York, 1847), or Alonzo Potter and George B. Emerson's *The School and the Schoolmaster* (New York, 1842), which covered the principles of education, method, hygiene, administration, and school management within the limits of four or five hundred pages. These two books for a long time held the field, the first being republished in 1885 by W. H. Payne. As in most fields of study, no universal plan or system prevails in America in the study of education. All manner of courses are found, between institutions like Teachers College, Columbia University, and the School of Education, Chicago University, on the one hand, and the small college on the other. History of education, psychology, principles, and methods of education are offered in nearly all institutions. It has remained for the larger institutions with greater wealth and better equipment to differentiate, so that they are able to offer preparation for elementary and secondary teachers, supervisors, superintendents, college teachers, and special subject teachers, as well as to supply the needs of the student who wishes to undertake important research work in education, and to the extent of establishing traveling scholarships for the study of comparative systems of education. The following instances are cited merely by way of example to illustrate both institutions which are recognized as the most important and those which may be said to offer average facilities. In each case only those courses which deal purely with some aspect of educational study are mentioned, the correlated courses in other departments being omitted.

*Teachers College, Columbia University.* — History and principles of Education: history of education in modern times; the educational theories of Herbart and Froebel; social and philosophical foundations of Greek and Roman education; history of education (graduate course); history of education in the United States; history of education in England; the historical foundations of modern education.

Philosophy of Education: logic as applied to teaching; social life and school curriculum; fundamental principles of education; educational sociology; philosophy of education (graduate); the public school and democracy; historic relations of philosophy and education; philosophy and sociology of education.

School Administration: comparative education; organization and administration of school systems; comparative education (advanced course); administration of public education in the United States; current problems in elementary education.

General and Educational Psychology: the applications of experimental and physiological psychology to education; readings in educational psychology; the psychology of childhood; psychology and education of exceptional children; educational psychology; the psychology of elementary school subjects; the application of psychological and statistical methods to education.

Secondary Education (general and advanced courses): secondary education in Germany; problems in secondary education.

Theory and Practice of Teaching in Elementary Schools: criticism and supervision of instruction in the primary school; supervision of instruction in the elementary school; the relationship of the kindergarten to the primary school; criticism and supervision of instruction in the elementary school; special problems in the theory and practice of elementary education.

Kindergarten Principles: theory and practice of kindergarten teaching; curricula of kindergarten normal schools and problems in kindergarten supervision; gifts and occupations; songs and games; stories; design in kindergarten; play and games.

Religious Education: introduction to religious education; the Sunday school; the principles of moral education; the analysis of religious phenomena.

In addition the theory and practice of teaching special subjects such as biology; domestic science; English; fine arts; French; German; geography; history; Latin; manual training; mathematics; music; nature study; physical education; physical science.

*Chicago University.* — History of Education: history of education (elementary); history of European education (ancient and medieval periods); history of European education (modern period); history of education (modern period); history of American education.

Administrative and Social Aspects of Education: school administration (introductory course); school supervision; state and municipal school systems; state school administration; the schools of Germany, England, and the United States; methods of organization and instruction; administration of secondary education; problems in secondary education; the course of study in the elementary schools; curriculum; the school and the community; special schools and supplementary social agencies; philosophy of education; moral education; general principles of fine and industrial art; industrial education in public schools.

Educational Psychology and Mental Development: educational psychology (introductory course); educational psychology (advanced); individual psychology; elementary genetic psychology; child study; introduction to experimental education; experimental education; the psychology of reading; the psychology of writing; educational tests; genetic psychology; experimental problems in education.

Educational Methods: general principles of methods; principles of method for elementary teachers; principles of method for high school teachers; survey of special methods in elementary education; criticism and supervision of teaching; development of modern methods of teaching in elementary schools; practice teaching.

General Principles and Special Problems of Education: principles of education; public education in America; principles of education; advanced principles of education; current problems in education; German pedagogy; mental deficiency and retardation in school.

Religious Education: history of the Sunday school; introduction to religious education; the materials of religious education; methods of teaching the Bible.

Kindergarten Education: kindergarten theory and practice (elementary); principles and methods in the kindergarten; theory and practice (advanced); the kindergarten program; critical study of the kindergarten program; kindergarten observation; Froebel's educational theories; plays and games.

In addition the theory and practice of teaching special subjects such as history; home economics; Latin; German; mathematics; English; physics; geography; natural science; elocution; children's readings and school libraries; hygiene and physical education; music; aesthetic and industrial education.

*Harvard University.* — History of educational practice and theories; the history of education in Europe since the Reformation; introduction to the study of

education; school administration as a branch of municipal affairs; modern theories of education; the education of the individual; educational theory in the early nineteenth century; organization and management of state and city schools and school systems; secondary education, public high schools, endowed and private schools; elementary education, programs of study, equipment, administration; the theory of statistical work and the application of statistical method to education; contemporary problems in education; the evolution and present status of education in certain selected states.

*University of Texas.*—School management; the process of teaching; principles of education; psychology of education; psychology of development; history of education; philosophy of education; abnormal psychology; psychology of adolescence; courses of study and organization of high schools; school supervision and administration; seminars in psychology and history of education; teachers' courses in mathematics, botany, Latin, history, physics, physiography, German.

Similar courses, if not under similar names, are found at the University of Michigan, University of Wisconsin, and Cornell University, with some additions which may be mentioned; Michigan offers courses also in school hygiene; educational theories of the Greeks; comparative school systems; history of educational systems in America; social education. Wisconsin has comparative educational administration; experimental education; contemporary educational movements. Cornell provides courses in experimental investigation; school hygiene; and industrial education.

These courses are intended both for graduate and undergraduate study. In addition to the opportunities for advanced study of education in colleges and universities, the teacher in service and the student may continue their educational research in the numerous teachers' voluntary associations (*q.v.*), local, state, and national; in teachers' institutes (*q.v.*); reading circles (*q.v.*); summer schools, the majority of which cater specially for the teachers' needs and furnish many of the courses specified above. Of wide scope and influence are the National Education Association (*q.v.*), with its many departments and its annual publication; the National Society of College Teachers of Education; the National Society for the Scientific Study of Education; Section L (organized 1906) of the American Association for the Advancement of Science. The number of national journals (*q.v.*) and the annual bibliography published by the United States Bureau of Education both testify to the extent of educational research in this country. Further, the study of education is considerably advanced by the numerous commissions (*q.v.*), education boards such as the General Education Board (*q.v.*), and foundations of the nature of the Carnegie and Sage Foundations (*qq.v.*). See, especially, TEACHERS, TRAINING OF; also EXPERIMENTAL PEDAGOGY; EXPERIMENTAL SCHOOLS; HISTORY OF EDUCATION; PHILOSOPHY OF EDUCATION; PSYCHOLOGY, EDUCATIONAL; and the articles on the various national systems.

**EDUCATION AND CRIME.**—The theory that knowledge and right action belong together is old in the world, and more than one epoch of human history has variously emphasized its deep faith in the possibility of the realization of this ideal. The story contained in the etymology of such terms as *barbarian*, *heathen*, *boor*, *villain*, etc., indicates how racial and caste feelings have first assumed that ignorance and then something worse, such, *e.g.*, as vice and crime, attached naturally to certain social and environmental conditions which were without the pale of national or urban "culture." The attribution, on the part of the city dweller, of ignorance to the peasant and the mere country man helped the "edu-

ated " for ages to shut their eyes to the increasing " wickedness " of the great aggregations of human beings becoming more and more numerous as the civilization of modern times demanded this expression of its expansive life. But, on the other hand, the longer memory of the country folk recalled the time when cities were altogether unknown, and blamed the iniquities which were perceived in a culture constantly becoming more complex on the very conditions of urban life itself, and declared, with the poet, that God made the country, but man (or the devil) the town. These two ancient views are reflected still in the explanations offered for the prevalence of crime in human society to-day. But it is idle to say that the question is settled by stating that the sole or even the chief factor in the essential criminality of children in particular to-day is the existence of the city, which has lost the old " purity " of the country; the " innocence " of the country, past and present, is fictitious and not real. To education, as a survival factor of mankind, the country offers quite as serious problems for solution as does the city.

Much philosophic thought about the matter has begun and ended with the famous words of Gray:—

"Where ignorance is bliss,  
'Tis folly to be wise,"

or the equally well-known lines of Pope:—

"A little learning is a dangerous thing;  
Drink deep, or taste not the Pierian spring."

Not a little of the discussion of the relations of education and crime to-day might be classified within these limits,—letting happy ignorance alone, and " drinking largely "; there being a considerable body of opinion to the effect that a smattering of knowledge is worse than none at all. After the democratic revolutions which marked the close of the eighteenth century, the development of popular systems of education (or some approach thereto) went on apace, and pedagogical philosophers saw in the expected triumph over the ignorance that had so long and so mightily prevailed among the masses the rapid disappearance of crime and its attendant evils, from which human society everywhere suffered so much. And in many authoritative quarters this optimism has continued unchanged down to the present moment. But the civilizing influence foreseen by Guizot, when he created the celebrated epigram " every schoolhouse opened closes a jail," has fallen far short of what was prophesied. The spread of education during the last century has not really been accompanied by a correspondingly marked and significant decrease in the amount of crime committed among civilized peoples; the great increase of knowledge among men has not occasioned a parallel decrease of the sort of

human wickednesses usually summed up as " crime."

It may be that the rôle of education as a preventer and a suppresser of crime and of criminal tendencies has been very much exaggerated, and it is not by any means as powerful a factor for the amelioration and improvement of the race as has been believed; or, perhaps, the educational systems in vogue are chiefly at fault, and we have not yet discovered the methods by which the evolutionary forces may be made most of for the formal advancement of the individual and of society. Certain it is, that the perceptible, direct influence of education in this matter and its service in the abolition of crime and criminality have fallen far below the hopes and estimates of the enthusiastic champions of popular education in the first half of the last century. It may also be said that some forms of crime have been increased by the growth of popular education, or have waxed stronger in spite of it, while some new ones even have been added to the category, not as mere proscribed offenses due to new laws of very doubtful wisdom or necessity, but as the immediate result of the increase in the spread of knowledge itself. And, if there is taken into account the progress in morality, especially, that seems to occur secularly, irrespective, apparently, of the particular forms of human institutions, etc., it may be argued also that the indirect effects of education have likewise been far less than had been confidently and generally expected. Drs. Bianco and Gandolfi, in their discussion of the efficiency of the school in the struggle against crime, emphasize the failure of popular education throughout the civilized world to justify the optimistic predictions once made in its behalf. Statistics from various parts of the world (particularly certain regions of France and Portugal) indicate that the wealthier and better educated classes are proportionately more criminal than the poor and the ignorant or illiterate. This, to be sure, is not true everywhere, but there is enough of it to make one doubt the adequacy of modern educational methods in coping with the situation. Increasing criminality is doubtless due in part to the growing individualism of the times, the spread of urban environments, and the exploitation of child life in innumerable new ways, etc. The school, evidently, does not furnish to the child, withdrawn for so long a time as modern educational methods have now made necessary from the home, an effective defense against that home which reflects the economic and material spirit of the times, and besets the returning scholar with suggestions and temptations, which the mere intellectual equipment given by the state is often utterly powerless to combat or to counteract. It is many times true also that the home, bad as it is, is more human than the school, and, therefore, more influential socially;

it has in it, naturally, more of the life of the child, and when it comes to a break with one or with the other, instinctively the child is home-led and home-suggested, or adult-led and adult-suggested in that environment, and not in the scholastic one. It is quite evident that the school, if it is to replace the home, must be an evolutionary and not an artificial substitute. Children often turn into criminals because the environment which makes them so is so much more human than that which seeks to make them scholars. Evidently, in our own day, crime modifies itself sufficiently, in many cases, to obtain the sympathy of the home, and thus survives in spite of the efforts of the school, which has not yet learned how best to make knowledge serve righteousness. Ferriani, the distinguished Italian criminologist, who made a special study of juvenile offenders, does not hesitate to say that "an ignorant honest man is worth a thousand educated rascals," and that, while the elementary schools may be increasingly useful in the amelioration and the prevention of crime and criminal tendencies, excessive education may play an important rôle in developing the genus of crime in children more or less degenerately affected. It is, indeed, he says, the educated classes who, in many respects, are the very worst offenders; it is hard to estimate the total effect upon society of "their conventionalities, white lies, opportunism, loose ideas of morals and justice, defiance of law and neglect of necessary duties, etc." Needless education, likewise, makes doubly dangerous the love of money, a weak conscience, hypocrisy, and other human failings. The bad example of state, school, and family, "the protective trinity of childhood," seems often more contagious and more infectious than the good done or capable of being done.

Ciraoli, moved by his investigations into the life and experiences of the evil women of the city of Naples, made this interesting statement: "The most notable institution for moral discipline is the home, the second the school, the last the city, the teacher of practical life. If a woman finds herself in the last, without having made a sufficiently lasting stay in the first, her moral education lacks its foundation, and the preparation in school is not enough to afford resistance against the charm with which city life has surrounded what the theologians call sin." This applies largely to men also; and to a considerable portion of the country as well as to the modern urban community. It is possible that the school city, the "Junior Republic," and other experiments along a similar line now being worked out in America, may contribute much to the solution of the crime problem, but they must keep in closer touch with the home than they seem to be doing in many cases, if they are to be real factors in the struggle against crime and vice of all sorts.

De Lanessan also points out the crimes and offenses condoned by special classes in the community: the loitering of workmen on their jobs, the watering of wine by otherwise honest peasants, the cheating by grocers and other merchants large and small, breaches of trust, sharp practices in the various professions, etc., the "crimes" of labor, which are all of considerable influence upon the family of the adult who is guilty of them, and upon the young of both sexes, who early learn the existence of such things, and soon become dishonest enough to condone or to copy them.

The ethical dualism that prevails in so many quarters of modern civilization is responsible, many think, for not a little of the failure of education to unify the morals of children and youth. Here the effect of bad example is most marked and most notorious. Proal, in his *Political Crime*, has discussed this question in detail, especially as related to politics and social procedure. The prevalence of smuggling, tax-dodging, cheating the government in innumerable ways, ballot-box stuffing, forgery, embezzlement, etc., among educated people; the defiance of law and order and the invasion of individual and personal rights by students in schools and colleges; frauds in examinations, athletic contests, etc.; the "criminal" *esprit de corps* of secret societies and like organizations; the use of the lottery in the name of charity and the church; the creedal opportunism of ministers of the Gospel; the "honorable" lying of the gentleman; the deceiving of women by men before and after marriage; the deliberate concealment of necessary facts from children, and the substitution for these of useless and even dangerous fictions,—all this practically assists in the survival, perhaps also in the creation, of crime in a way few people commonly think of. It is a perilous crisis for the child, when he discovers that those whom he has trusted have been deceiving him, even father and mother. And no school exercises at present existing are capable of restoring what has thus been lamentably undone. If adults would remain honest and honorable, there would be few, if any, criminal children.

Dr. Albert Wilson, one of the most recent of British authorities to treat the question, says in his book, *Education, Personality, and Crime* (p. 147): "As a critic of state methods, I should say that the three R's have filled many a prison. Most of the criminals examined have passed average standards; some have done well. In none have I found school influence producing any valuable effect. Had they been in good private schools, some would probably have been saved, and the others would have been better without the three R's. Instructed degeneracy is a formidable weapon against peaceful communities. In olden days, the illiterate used their intelligence or associative powers with more useful results, and were

far happier; whereas now the same class fill their minds with penny dreadfuls and improper subjects, and suffer from a mental auto-intoxication. What will become of us if the religious and moral training is expunged from the already imperfect, undeveloped system? Crime is not lessened by teaching that it is wrong to steal. It is the effect of reasoning and demonstration which prevents crime. We must associate on the mental screen pictures of the horrible nature of such actions and the dangerous consequences. When the temptation arises in the sensory centers, and desire is followed by choice, the well-stamped moral and religious 'associations' may dictate a choice which is at the same time prudent, wise, and righteous."

Dr. Wilson in *Education, Personality, and Crime* believes that decrease of crime is due not so much to board schools as it is to social improvements, — children are not "born tired," but are *made* so by the State, which, moreover, destroys individuality and dwarfs personality. He goes so far as to say (p. 143) that the State has sinned "in destroying private schools, which represent the ideal system." He is also of the opinion (after years of observation) that "children should have a sound religious training," but one neither dogmatically sectarian nor controlled by "men's traditions." Instruction by the State, however, cannot be a substitute for education by the parents from the cradle; and free street play is often far better than compulsory school attendance; food for the body must always precede food for the mind. It must be remembered, too, that "crime is always changing with the times, as are also the indictable offences, and the quantitative and qualitative methods of administration." What education has really done Dr. Wilson sums up thus: "Crime has its fashion, and must be up to date, or it would die out. Crime aims at being a science as well as a refined art; the older clumsy and often brutal methods are passing away, and this alteration, one freely admits, is due to modern education" (p. 13).

The view that much of crime is "due to bad education, to bad example, to city life, etc.," is set forth by Dr. Lebas, who emphasizes the rôle of education, preventive and reformatory legislation, and the efforts of society to correct and abolish evils and suggestions of evil for which it is itself responsible. Another very recent monograph along similar lines is Dr. J. L. de Lanessan's *The Struggle against Crime*, the core of whose argument is the following: "The opinion that all abnormals or degenerates must be more predisposed toward vice and crime than normal individuals cannot be accepted. For everybody to be honest, all that is needed is to give them a physical and a moral education as well as possible adapted to the organic and physiological conditions in which each one

finds himself." It is a mistake to think that, with progress from savagery to modern civilization, vice has disappeared from human social communities, — what has really happened is simply that the number of vicious individuals has decreased. Another mistaken idea, according to de Lanessan, is that crime is hereditary, whereas it is merely a question of "bad family education." When the toll of bad education and bad example has been taken, there is little left to dispute about; with good education and good example, crime would practically disappear altogether. De Lanessan is in favor of a maximum of State interference for the protection and education of children. While there is no necessary criminal tendency in very nervous and excitable children, an exceptionally good education ought to be provided for them; and all children whose parents or adult maintainers are away from home too long to make them proper guardians should be attended to by the State. As a means of self-defense, society has the right (and ought not to be hindered in the exercise of it by any considerations of free will, moral responsibility, punishment, etc.), to remove from contact with criminal or vicious parents (and other adults), and from environments suggestive of crime and vice, all children in danger of developing into useless or evil members of society. As to juvenile criminals, he believes that all such appearing before the courts should be sent to special schools (industrial, military, etc.), where they should remain until they become of age for military service, from which they might be supposed to benefit. De Lanessan is more optimistic than many concerning the effects of "good education" in the abolition of vice and crime, and exaggerates the results of "bad education" as an actual factor in the production of criminals. Like some other writers of similar tendencies, he does not recognize the factor of personality, which, in criminal as well as in normal actions, is of great importance.

Overemphasis upon education as a preventive of, or a cure for, crime and criminal tendencies has sometimes come from hard-and-fast acceptance of the theory that anatomical type, language, and culture were originally closely correlated, and have in essentials remained so since. In America to-day education as a possible "crime cure" suffers not a little from the "biological basis" of much of our machinery of instruction, and the attempt to see in the development of intelligence in the race and the individual "stages," "periods," "phases," "epochs," etc., corresponding to other alleged successive epochs or stages in psychical and bodily growth in man and the other animals. The attempts to base reformatory education on the "recapitulatory theory," the "three stages of culture (hunting, pastoral, agriculture)," are in some respects worse than the efforts to utilize them

in the normal courses of instruction. The "three-stage" theory of the evolution of human culture is now discredited by the best anthropologists and ethnologists, as Professor W. Lay and Professor H. I. Smith have recently pointed out, and its employment as an education panacea must soon end. Little hope exists of preventing the appearance of crime among children (inferentially also among adults) by the use of methods dependent upon wholly false or partly false interpretations of the course of human evolution in the race. If there is any parallelism between the history of the individual and the race, those methods only can be of essential value in educating the individual which really correspond to phenomena in the racial past, and not to such as are presumed or imagined. The ideas that children represent the past of the race, and that they tend to represent the worst of it have been overworked in connection with very modern educational theories. "Back to nature," country life, manual training, physical culture, industrial education, etc., while all, doubtless, of value in certain ways, are, nevertheless, not panaceas for the eradication of crime any more than they are infallible guides for the normal development of the sane and healthy individual. Their failure to solve the problem of normal education prepares us for reasonable skepticism as to their effects upon the abnormal and the so-called degenerate. In the grasp of the pedagogue and the reformer they lose too much real generic humanity to be thoroughly effective with the most generic of all human beings, the child. And it sometimes seems as if the ultimate solution of the problem was put off still further in the future by the exploitation of so many special "fads."

Lombroso, the father of modern criminal anthropology, once said, concerning education and crime: "Education can prevent a good nature from passing from infantile crime to habitual crime, but it cannot change those who are born with perverse instincts." This view of the matter gives us two prime sources of criminals, the children who by nature are temporarily or transiently criminal, and those who are "born criminal" inevitably. Even if education did nothing but save normal children from becoming habitual criminals, its rôle in human social evolution would be very important. But it is almost inconceivable that education, which ought to sum up in itself the instructive, stimulative, restorative, and recuperative, not to say transmutative, powers of human wisdom and experience, should be altogether without influence upon those deemed "degenerate" or "abnormal" even from birth. The apparent failure is rather of system than of education itself, which all along has been utilized as a method of conveying and preserving certain sorts of knowledge rather than as a generic factor of human evolution and social progress. One may justly say of the results of the edu-

ational systems of to-day that the chief trouble with them is that "Knowledge comes, but wisdom lingers." Our youth, instead of being "rich in saving common sense," are, after being educated in the approved fashion of the times, so often really poorer in it than when they began. In acquiring something specifically racial, national, something peculiar to epoch or to social order, they have lost altogether or dwarfed into "innocuous desuetude" the generically human which stands above race, age, and class. In the course of culture progress man has been too tolerant of certain specifically evil things such, *e.g.*, as war and its attendant train of evils. And crime, perhaps, belongs in this category of too tenderly handled phenomena. This is very true, if we take the view, set forth by Tarde and others, that crime, like any other branch of social activity, nourishes itself to a considerable extent upon the economic conditions and theories, the educational doctrines, the philosophic and religious beliefs and speculations of the times. Like them, also, it gets local color, *esprit de corps et de l'âme*, submits to racial transformation, class modifications, etc. In fact, in so far as such a thing is at all possible, it varies in order to survive in a community, which, theoretically, is intolerant of such elements of its cultural make-up. The rôle of the school in the struggle against crime is not that of a theater of "mental discipline," but that of an environment corresponding, on the one hand, to the home, and, on the other, to the city and the State, so organized upon sympathetic lines that the child may pass from one to the other without loss or injury. In the ideal State the child must be at home without detriment to the acquisition of knowledge, and go to school without impairment of the home sense long enough to equip him for right conduct and complete activity in the State, of which the family must always be the firm foundation. From one point of view, at least, particularly in America, the question of education and crime resolves itself into a problem of the correlation of the home and the school. Indeed, this is the one thing necessary for education in general. Everything indicates that the school is assuming too much and the family acknowledging too little responsibility. This readjustment outweighs all questions of curriculum, methods of instruction, etc. When it is accomplished, many difficulties will disappear of themselves.

**EDUCATION COMMITTEE OF THE PRIVY COUNCIL.** — The grant of £20,000 made by the House of Commons on August 17, 1833, "in aid of private subscriptions for the erection of schoolhouses for the education of the children of the poorer classes" marked a new era of definite state intervention in the education of the people of England. This annual grant increased steadily, until to-day it exceeds £12,000,000. The grant of 1833 was administered by the Treasury under a minute dated Aug. 30, 1833. The Treasury continued to administer the annual grant until Apr. 10, 1839, when a board, being a committee of the Privy Council, was appointed "to superintend the application of any sums voted by Parliament for the purpose of promoting public education." This committee continued to administer those funds, and pursued a progressive policy until the year 1856, when the increase of the work of the committee of the Council necessitated the appointment of a Minister of Education and the creation of an Education Department. By an Order in Council of Feb. 25, 1856, (confirmed by statute the same year), the Education Department was formed and comprised the Educational Establishment of the Privy Council Office and the Department of Science and Art which had had its origin in the report of a select committee of the House of Commons, which in 1836 recommended the establishment of schools of design, a matter that was taken up by the Committee of the Privy Council for Trade. In 1856 the grant for this purpose was £64,375. In 1852 the Board of Trade had constituted a Department of Practical Art with a Science Division. The two departments, though both under the Education Minister, remained separate, and when in 1899 they were amalgamated in the Board of Education formed by statute in that year, the science and art grant was £587,793. The act that formed the Education Department in 1856 enabled the Crown to appoint a vice-president of the Committee of Council on Education who could sit in the House of Commons and thus keep the people in direct touch with national elementary education. Thus, until the Board of Education was formed in 1899, the president of the Council represented education in the House of Lords, while a vice-president of the committee represented it in the House of Commons. The Privy Council thus controlled national elementary education until the year 1899. The history of the policy of that Council which resulted in the act of 1870 and 1876 (throwing the responsibility for education partly on the local rates and making education compulsory) and the act of 1891, which made elementary education free, needs to be treated in detail by the student who

**EDUCATION AND INSTRUCTION.** — The distinction between education (*Erziehung*) as a wider process and instruction (*Unterricht*) as a narrower one has been especially developed in German pedagogical theory. Education is essentially a moral and social process; it consists in the operation of all the influences, conscious and unconscious, that shape character and give direction to the affections. Instruction denotes one of the means of education, viz. the use of intellectual training in the formation of character, discipline, school life and government being the other. From the standpoint of this distinction, the discussion (raised, for example, by Herbert Spencer) as to whether education can modify character is meaningless; if it does not affect character, it is not education. Properly put, the question is how teaching and learning in their definitely intellectual aspects shall be made contributory to character forming. The problem is the more serious because, while it is almost universally admitted that the final aim of education is moral, most of the time of the schoolroom is spent concretely on matters of intellectual acquisition. If, then, instruction is not made to contribute effectively to education, the professed aim of the latter is sure to be missed. J. D.

**EDUCATIONAL ASSOCIATIONS.** — **General.** This term may be and is quite frequently applied to include a great number of organizations of teachers of recent times, though the term Teachers' Voluntary Organizations (*q.v.*), is more accurate. It may also include that type of organization dating back to the close of the Middle Ages, which aimed to organize a teaching force to improve the general intellectual, social, and moral conditions of the people. Most of these latter have been religious in their motive and ecclesiastic in their origin. Hence the term Teaching Congregations (*q.v.*) would accurately describe those which arose preceding and immediately after the Reformation. These are discussed under the appropriate titles. The remainder of those societies mentioned in the section following are also religious in character, but the membership is not composed of teachers. They are not teaching orders, but associations for the promotion of education. To these the

term "educational society" may be appropriately applied. The most important of these are also discussed briefly under the appropriate separate titles. But the term "educational association" is also used to describe the type of organization which grew up in most countries in western Europe and in the United States in the early part of the nineteenth century for the encouragement of popular interest in education and for the improvement of school conditions. Such associations grew out of the same general condition which produced the public educational systems of this period. The fact that the German states were better provided with public school systems than the other countries mentioned is an explanation of the slighter importance of such organizations there. Such as existed were minor or local associations, looking toward specific educational reforms such as those of Basedow and the advocates of physical education.

After the middle of the nineteenth century these associations generally developed into associations for teachers; either of a general scope or of teachers of the highly specialized phases of education. Such associations will be treated under the caption TEACHERS' VOLUNTARY ASSOCIATIONS. More recently, associations for general educational propaganda are again becoming prominent. These are usually devoted to the promotion of special educational causes, such as moral or industrial education. (See RELIGIOUS EDUCATION ASSOCIATION; etc.)

It is difficult to say with certainty what was the earliest of the various European voluntary societies for promoting education among the poor, but it probably was the society founded by Gerard Groote at the end of the fourteenth century and known as the Brethren of the Common Life (*q.v.*), the society to which Thomas à Kempis owed his education. At the end of the sixteenth century (1599) the Jesuits (*q.v.*) had brought their method (*Ratio Studiorum*) to perfection, and had then been at work with this end in view for fifty years. The society founded by César de Bus in 1592 near Avignon and known as *La Congrégation de la Doctrine Chrétienne* probably paved the way for later societies that limited their work to the education of the poor. The Oratorians (*q.v.*) and the Port Royalists (*q.v.*) in the seventeenth century had a larger goal than this, and certainly an outlook that had in it more of the Renaissance ideal than was presented by the Jesuit method. The Institute of the Brothers of the Christian Schools was founded by St. Jean Baptiste de la Salle on May 27, 1684. About the same date as the French and English societies must be placed Francke's (*q.v.*) work for poor scholars at Halle.

**England.** — The history of educational associations in England is peculiarly the history of the development of elementary education. Purely professional societies are of more recent growth than societies for the promotion of the

education of the masses. But the last few decades have witnessed the rapid rise of societies, professional and lay, for the advancement of every phase of education. Probably the earliest association of importance in the history of English education was the Society for the Promotion of Christian Knowledge (*q.v.*), founded in 1698 by Dr. Bray. In 1785 the Sunday School Society was established, and soon met with great success both in the number of pupils reached and the number of teachers employed. The two societies which laid the foundations of the present system of elementary education were the British and Foreign School Society (*q.v.*), founded by Lancaster's friends in 1808, and the National Society for Promoting the Education of the Poor in the Principles of the Established Church (*q.v.*), established by Dr. Bell in 1811. A third society of a similar type was the Christian Instruction Society founded in 1825 to represent the views of Baptists and Independent Dissenters. Irish education was promoted, among other associations, by the Kildare Place Society (*q.v.*), for undenominational education, founded in 1811, and the London Hibernian Society, established on Protestant principles in 1816. In 1836 was founded the Home and Colonial Infant School Society (*q.v.*) which trained teachers for infant schools. The Central Society, founded in 1837 by Sir Thomas Wyse and others, collected and published educational information of a statistical, historical, and descriptive character. In 1844 the interests of ragged schools, especially in London, were promoted by the Ragged School Union. In 1848 the recently formed Congregational Board of Education arranged for a series of lectures to propound the views of the Board. The course was delivered at Crosby Hall, and was well attended. They were published in 1848 as the *Crosby Hall Lectures on Education*, which contain objections against government action in education, and the advantages of voluntary effort. The years from 1850 to the passing of the act of 1870 are full of interest in the history of educational agitation and associational activity, much of which coincided with the democratic movement in the north of England. The Lancashire Public School Association was founded in 1847, and in 1850 assumed the title of the National Public School Association, for the establishment of unsectarian rate-aided schools under a democratic system of government. In the same year (1850) the Manchester and Salford Committee came into existence to maintain the opposing side of sectarianism. In 1869 the National Education League was launched in favor of unsectarian public education, and was opposed by the formation in the same year of the National School Union, which stood for denominational principles. Many of the associations which appeared during the period of agitation went out of existence as soon as their objects were achieved.

Other societies which interested themselves in the promotion of general education also arose during the nineteenth century, among which the Society for the Diffusion of Useful Knowledge founded in 1825 by Lord Brougham must be mentioned. The National Home Reading Union (*q.v.*) was established in 1887 to stimulate and direct home reading; and in 1903 the Workers' Educational Association (*q.v.*) came into existence for the promotion of higher education of working men and women. The Recreative Evening Schools Association (1886) has for its object the creation of public interest in and the establishment of continuation schools of a practical and recreative kind.

Organizations of another type are associations for the promotion of public and professional interest in the scientific study of education. One of the earliest of these was the Education Society, founded in 1875 "for the development of the science of education," and since 1889 amalgamated as a section of the Teachers' Guild, itself a national organization established in the interests of the teaching profession. Established as early as 1846, the College of Preceptors (*q.v.*) sought to advance the interests of education by training and certifying teachers. The Parents' National Educational Union (1891) seeks to disseminate among parents the best principles of education and training children and bring the home and school into close sympathy with each other. The Child Study Society has a membership of parents and educationists for the study of mental and physical condition of children and of educational methods. The aims of the Moral Education League, founded in 1897, are obvious from the title of the society. Since 1901 the British Association has devoted a section (Section L) to the discussion of educational topics, which has gained in strength and importance every year. The contribution of the North of England Council for Promoting the Higher Education of Women (1867-1874) to the cause which it espoused must also receive mention. The Froebel Society (1874) and the National Froebel Union were founded in the interests of the education of young children, the latter organization granting certificates to teachers through its examining board.

Teachers' professional associations have developed largely within the last fifty years, or even less. These will be discussed under the title **TEACHERS' VOLUNTARY ASSOCIATIONS.**

**France.** — Associations of teachers for the study of educational questions may be divided into three classes, none of which is devoted solely to the study of these questions.

1. Associations of professors or instructors organized for the defense of their professional interests, for mutual assistance, etc. They also study questions of instruction and school discipline, pass resolutions on the curriculum, estimate the comparative value of different books used in the school, etc. An example of

this type is the Educational Society of Principals of Public Primary Schools in Paris (*Société Pédagogique des Directeurs et Directrices des Ecoles Primaires Publiques de Paris*). The discussions at their meetings are published in their bulletin. They exercise a sufficiently great influence on education, since the principals, to a certain extent, are free in their own schools to employ such methods as seem preferable to them.

2. Associations or leagues for the improvement of hygienic conditions or scientific methods of instruction. These societies include at the same time teachers, parents, medical men, philanthropists, etc. They discuss the social value of methods of instruction, the best arrangement of the curriculum, the utility of certain measures for the improvement of school hygiene, the health of the pupils, etc. They have no direct influence on the school, although they have teachers among their members. But they lay their views before the public authorities which examine them for any hints they may offer. Typical of these associations is the League of Doctors and Families (*La Ligue des Médecins et des Familles*), established in 1902 for the improvement of physical and intellectual hygiene in the schools. It organizes national and international congresses for this purpose.

3. Scientific associations for the study of child psychology, the educational value of methods of instruction, etc. This membership includes at the same time teachers, scientists, and others who take a theoretical interest in educational questions. The teachers meet there to exchange the practical observations made in the classroom in return for the scientific views on the child given by psychology and physiology. The best known of these societies is the Society for the Psychological Study of the Child (*Société pour l'Étude Psychologique de l'Enfant*), suggested in 1902 by F. Buisson in the *Correspondence de l'Enseignement Primaire*, and organized in 1899 by F. Buisson, L. Marillier, etc. This society has branches in Lyons and elsewhere.

Other analogous associations devote themselves to the methods of teaching abnormal children, e.g. the *Société du Patronage Familial*, in which Dr. J. Philippe and Dr. Paul Boncour organized a medical-pedagogical clinic in 1902; the *Société de l'Œuvre de l'Enfance Anormale* established in Lyons in 1906 by M. Granvilliers, Professor Beauvisage, and others; and a society in Bordeaux founded in 1906 by Rector Thomin, Professor Regis, and others.

J. P.

**Germany.** — While there is no country where the teachers are more thoroughly organized, the broader type of educational associations, which is not specifically composed of teachers, has not been so important. This is due to the fact that several centuries earlier governmental activity had accomplished in the

way of establishment of public schools that which in America and England was left to popular propaganda during the early nineteenth century. The more important of these teachers' associations are discussed under TEACHERS' VOLUNTARY ASSOCIATIONS.

Outside of these general teachers' associations, there are many societies which are devoted to particular movements in pedagogy, such as the Herbart societies, to the study of methods in the different school studies, particularly drawing, gymnastics, manual training, etc.; or are engaged in the pursuit of economic or charitable objects for the benefit of teachers and their families. The last-named societies are often known as *Pestalozzervereine*.

There are many other associations for the promotion of particular objects, such as female education, industrial education, improvement of instruction in drawing, natural science, mathematics, modern languages, etc. Lastly there may be mentioned two large and widely extended associations with educational purposes, though not mainly composed of teachers, namely the *Allgemeine deutsche Sprachverein*, the object of which is the purification of the German language from unnecessary foreign words, and the *Allgemeine deutsche Schulverein*, which helps to establish and to keep up German schools in the Slavic and Hungarian parts of Austria, in South America, and in other parts of the world, where a German-speaking minority, living among a non-German population, needs to be assisted in its struggle to maintain its native language and civilization. A recent educational reform movement of great importance has given occasion to the formation of three societies which include numbers of people outside of the teachers' profession, associated with others from within the profession to secure the adoption of specific educational policies. The three associations most prominent in the agitation that brought about the changes in the secondary school system of Germany, and culminated in the conference of December, 1890, and June, 1900, are the *Verein für Schulreform*, established 1889, favoring radical changes, the *Gymnasialverein*, which is conservative, and the *Einheits-schulverein*, advocating a unification of school types, an organization of the moderate liberals.

The services to the cause of popular education in Germany rendered by these various associations, especially those of the teachers themselves, can hardly be overestimated. Through their collective efforts the intellectual, financial, and social condition of the teaching profession has been raised, the work of the schools has been steadily improved, and the respect for popular education on the part of the public, as well as on the part of the political rulers, has been greatly increased.

**United States.** — The American Institute of Instruction (*q.v.*), which was organized in 1830

and is still in existence, was the first educational association formed in the United States. Until the more recent developments of the National Education Association, it met the needs of a national organization; for while its membership has always been largely from the New England states, representative educational leaders in most of the states of the Union have always participated in its councils. The Western Literary Institute (*q.v.*), although contemplated as early as 1829, was not formally organized until 1831. It met an educational need in the Mississippi valley not unlike that supplied by the American Institute of Instruction in New England. Fifteen annual sessions (1831-1845) and three extra meetings were held. The American Lyceum Association (*q.v.*) was organized in 1831 and held its last annual convention in 1839. It aimed primarily to advance the interests of popular education through the establishment of public libraries, lecture courses, and museums. The American Association for the Advancement of Education (*q.v.*), which, in some important particulars, was the parent of the National Education Association, was organized at Philadelphia in 1849 and held yearly meetings until 1856. It was distinctly representative of the new state school systems which came into prominence at this time. The National Teachers' Association (*q.v.*), which was the immediate predecessor of the National Education Association, was organized at Philadelphia in 1857. The subsequent career of these associations will be given under **TEACHERS' VOLUNTARY ASSOCIATIONS.**

A still more recent development has been the formation of organizations of students interested in the technical study of education. Thus in 1895 was organized the National Herbart Society for the Scientific Study of Teaching. To this society is due much credit for the encouragement of scientific investigation and a more thoughtful consideration of educational problems. In 1902 this society broadened the scope of its interest and was re-organized under the title, National Society for the Scientific Study of Education. In 1902 was organized in connection with the mid-winter meeting the Department of Superintendence of the National Education Association, the National Society of College Teachers of Education. This society devotes its attention to the consideration of problems of organization and methods of collegiate and university departments of education. Section L, organized 1906, of the American Association for the Advancement of Science, is devoted to the discussion of education.

Special interests continue to bring into existence societies which are national in their scope, influential in their work. Among those of recent origin are the National Society for the Promotion of Industrial Education (1906); and the Society for the Study of Moral Problems of Education. Occasional congresses such

as the Congress of Social Education, Boston, and the Moral Education Conference (New York and Providence, 1911), serve a purpose similar to that of these associations, and differ only in the fact that the permanent organization is more in the nature of a committee which provides for meetings and a general attendance of what may be considered merely temporary members.

**EDUCATIONAL CONDITIONS, DIVERSITY OF.** — One of the most marked features of public education in the United States is the great diversity in the racial, economic, and administrative conditions which determine, in large part, what kind of an educational system can be maintained. So greatly do these conditions modify education that in no two states, and often in but few counties within a state, do approximately the same educational conditions exist. Even within the same county two different towns or cities frequently present quite different educational conditions. Still, notwithstanding these diverse conditions, certain similarities exist within certain geographical areas, and one frequently speaks of the educational systems of certain groups of states as presenting somewhat similar educational conditions.

Education in the New England states, for example, is perhaps most guided and in some respects encumbered by historical traditions, which not infrequently stand in the way of needed educational reform. Here one finds some of the best as well as some of the poorest of schools. Local taxation is highly developed here, but general taxation for a state school system, as opposed to a series of local school systems, is as yet in its infancy. Secondary education is well developed, but the state university is almost everywhere lacking. In both the North Atlantic group of states, which includes the New England states, and in the North Central states, we find a very mixed population, due to the fact that the greater part of our great foreign immigration has settled in the states of these two groups. The negro problem, however, is not marked here. The states of these two groups, too, are most advanced in manufacturing, trade, and industry, and the combination of these two factors has resulted in a dense and highly mixed population and in the development of large commercial and manufacturing cities, and has brought to the front some of the most complex and most difficult educational problems now confronting American school officers. In the North Central division in particular we find a very deep interest in education and a willingness to pay for schools. Secondary education and the state university are well developed here.

and the numerous educational associations and the large attendance at summer schools indicate a deep interest in educational problems on the part of the teaching staff. In the South Atlantic and South Central groups of states entirely different educational conditions exist. These states are not so densely settled, and are essentially rural and agricultural, and they have not as yet recovered financially from the ravages of the Civil War. High taxation here produces but a small income. The elementary schools are frequently very poor, and secondary education is only now in the process of development. In addition, all of these states have a large negro population, which in many counties exceeds the white population in ratios of two, three, and four to one, and for the negroes a separate school system must be maintained.

In the Western Division, which comprises the group of states extending from the Rocky Mountains to the Pacific Ocean, we find a sparse and scattered population, possessing large initiative, relatively large wealth, a strong belief in public education supported in large part by general taxation, much advanced legislation, and good schools. Some of the best rural schools in the United States are to be found in this Western group of states; there are many well developed secondary schools, considering the sparsity of the population; and the state university is everywhere a marked feature of the educational system of the state.

Many elements contribute to the formation of the educational attitude of a people, and many things condition the possibilities of properly supporting a school system. The presence or absence of good or bad historical traditions; the presence or absence of intelligent and effective leadership, resulting in good administrative conditions and good school laws; the presence or absence of natural resources, good climate, accumulated wealth, agricultural possibilities of a high order, and an intelligent and thrifty population; and the demands made upon the school system by the presence of diverse races or complex social conditions;—these are some of the important elements which modify educational conditions and limit educational possibilities, and these vary greatly in the different states and groups of states.

E. P. C.

For a more detailed statement of educational conditions in the different states, see the articles on the state school systems, as ALABAMA, ARIZONA, etc., under the subdivision *Educational Conditions*.

**EDUCATIONAL JOURNALS AND JOURNALISM.**—The earlier type of publications indicated by this title was quite different from

the educational journal of the present, designed for the members of the teaching profession. During the eighteenth century, magazines such as *The Teller* (1709) and *The Spectator* (1711) in England, and the *Moralische Wochenschriften* (1713) in Germany were designed to improve the general intellectual and moral condition of the people. Along with and following these, especially in Germany, appeared the various *Annals* and magazines designed to convey popular information and practical suggestions to the masses. During the latter part of the century publications of a similar character for children appeared in considerable number. Following these came a type of publications more distinctly educational in the narrower sense, since they aimed to furnish subject matter of instruction, of a more or less popular informational type, especially along the line of the natural sciences and the newer subjects, which as yet had not been well formulated as school subjects. Out of these in the early part of the nineteenth century developed the publications designed for the members of the teaching profession, now with the establishment of the public school systems grown in number and in importance sufficient to support publications of this character. However, even earlier magazines of the type, such as the *American Journal of Education* (1826-1830) and *The Annals of Education* (1830-1837) addressed a much larger public than the teaching profession, and aimed to arouse a public interest in education and to give information appealing to a much larger clientele. The entire subject will be treated more fully under the caption, JOURNALS AND JOURNALISM, EDUCATIONAL (*q.v.*).

**EDWARD III AND ENGLISH EDUCATION.**—See ANGLO-NORMAN DIALECT; ANGLO-NORMAN SCHOOLBOOKS; BLACK DEATH AND ENGLISH EDUCATION, THE.

**EDWARD VI, KING OF ENGLAND** (1537-1553).—Born Oct. 12, 1537, he was only

nine years old when he came to the throne, and only fifteen when he died. Yet he has been held up for worship as the patron saint of Protestant learning, and reputed as the founder of the whole system of English secondary education, the inventor and donor of the Free Grammar Schools, the public schools of England. Edward was undoubtedly a well-educated boy, overeducated, indeed, under Dr. Cox, ex-headmaster of Eton, described by Ascham (*q.v.*), in the *Schoolmaster*, as "the best teacher and greatest beater of our time," and his exercises and essays show a remarkable precocity. But it is obvious that a boy of nine, however precocious, could have had no influence on public affairs, or on the act for the dissolution of colleges and chantries passed in the first year of his reign, which gave occasion for the false reputation he has enjoyed. This act abolished all the colleges, chantries, guilds and hospitals, except the cathedrals, the colleges in the universities, and Eton and Winchester as part of the universities, and confiscated their property to the Crown. This meant the confiscation of the endowment of nine tenths of the schools in England, as they nearly all formed part of or were attached to such colleges and chantries. The act indeed provided for the appointment of a commission to continue the grammar schools and assign lands out of the confiscated property for their endowment. But as there was not time, nor, in the financial straits of the public purse at the time, inclination to assign endowments, the grammar schools were continued only till further order, with salaries to the masters of the net amount which they were actually receiving from the endowment at the time of the dissolution. The song schools, which did the work of elementary schools as reading as well as music schools, were swept away. In three or four cases of quite recent foundations, such as Berkhamstead, Herts, the confiscated endowments were at once restored by act of Parliament in the same year, 1548. In perhaps a dozen cases they were restored or other lands given instead to the corporations of towns, who bought back the guild lands or were incorporated to take the place of dissolved guilds, as in the case of Shakespeare's school at Stratford-on-Avon. In about twenty cases special bodies of trustees were incorporated as "Governors of the goods possessions and revenues of the Free Grammar School of Edward VI in the town of Sherborne," or wherever it might be, and were granted sometimes by purchase, sometimes by way of gift, lands belonging to dissolved chantries or guilds, not the same which had belonged to them before, for they had been sold, but lands of other chantries which for some reason had remained unsold. The credit of the refoundation of the scanty few thus re-founded must be given to John Dudley, Earl of Warwick and afterwards Duke of Northumberland, who had

ousted from power and executed the Duke of Somerset, Edward's uncle, the Protector, and ruled in Edward's name from 1550 to 1553. A certain number of re-foundations already arranged under Edward were actually carried out under Queen Mary and received her name. The only school foundation in which Edward had any personal share, and that was a very subordinate one, the real founders being Ridley, the "martyr" Bishop of London, and Lord Mayor Dobbs, was that of Christ's Hospital, London. This was founded not as a grammar school but as a foundling hospital, as part of a great scheme of poor relief, and was endowed entirely by the subscriptions and donations of the citizens of London.

Edward VI has, therefore, no claim whatever to be regarded as the founder or promoter of education. Educationally his reign was signalized chiefly by the spoliation of some 300, and the subsequent re-endowment of some thirty schools.

**EDWARD WATERS COLLEGE, JACKSONVILLE, FLA.**—A coeducational institution established in 1883 and maintained under the auspices of the Methodist Episcopal Church of Florida for the education of colored students. Theological, classical, scientific, normal, English, business, bible and music courses are offered. The entrance requirements are equivalent to about four points school work. Degrees of B.D., A.B., B.S., are conferred. There are seven instructors on the faculty.

**EDWARDS, BELA BATES (1802-1852).**—Active in religious education; was graduated at Amherst College in 1824. He was tutor at Amherst, secretary of the American Education Society (*q.v.*), editor of the *Quarterly Journal of the American Education Society*, and professor in the Andover Theological Seminary. Author of the *Eclectic Readers* (1835).  
 W. S. M.

**EDWARDS, EDWARD (1812-1886).**—One of the most active promoters of the public free library movement in England. He was for a time supernumerary assistant in the department of printed books in the British Museum. About 1846 he collected library statistics at home and abroad and published them in the *Athenaeum*. He thus attracted attention, and when the committee of William Ewart (*q.v.*), met to discuss the question of free libraries, Edwards was one of the principal witnesses. He was instrumental in opening the first library

maintained out of town rates at Warrington in 1848. In 1850 he was appointed the first librarian of the Manchester Free Library (opened in 1852), where he remained for eight years. He promoted improvements in libraries and librarianship. His works are important contributions to the history of libraries. They include *Memoirs of Libraries* (1859); *Libraries and their Founders* (1865); article, "Libraries" in *Encyclopædia Britannica* (1869); *Free Town Libraries* (1869); *Lives of the Founders of the British Museum* (1870). In 1883 Edwards was placed on the Civil List. He died in 1886.

ALLEN, A. V. G. *Jonathan Edwards.* (Boston, 1889.)

**EDWARDS, JONATHAN** (second) (1745–1801). — The second president of Union College; was graduated at Princeton in 1765. He was active in a movement looking toward the education of the Indians, and was president of Union College for two years (1799–1801).

W. S. M.

**EDWARDS, RICHARD** (1822–1908). — Schoolman, educated at the Bridgewater (Mass.) Normal School and the Rensselaer Polytechnic Institute. He was instructor in the Bridgewater Normal School (1848–1853), principal of the high school at Salem (1853–1854), principal of the Salem Normal School (1854–1857), of the St. Louis Normal School 1857–1862), and of the Illinois Normal School (1862–1876). He was state superintendent of Illinois from 1887 to 1891. Besides numerous papers on educational subjects, he was the author of a series of school readers and for several years editor of the *Illinois Teacher*. W. S. M.

**EDWARDS, THOMAS CHARLES** (1837–1900). — Welsh divine who became the first principal of the University College of Wales at Aberystwyth in 1872. It was due to his efforts mainly that the institution met with success in spite of the numerous financial difficulties with which it was beset. Edwards took an active part also in promoting the success of the University of Wales. In 1891 he retired from Aberystwyth and became principal of the Cal-

vinistic Methodist Theological College at Bala. In 1898 his services to the University of Wales were recognized by the conferment of the first degree of D.D. granted by that body.

**EFFERENT.** — The term signifies "carrying from." Efferent nerve fibers are those which carry stimulations from the central nervous system back to the muscles or other organs at the surface of the body. Efferent fibers are synonymous with motor fibers and are opposed in kind and function to afferent or centripetal fibers, the latter carrying the stimulation toward the central organs. C. H. J.

See NERVOUS SYSTEM.

**EFFORT.** — Effort implies the putting forth of energy in reaching an end. But not all such expenditure of energy is effort, for it may be easeful or habitual. Effort implies in addition a factor of labor, toil, pain, struggle in the surmounting of obstacles, or overcoming of difficulties, which lie between the agent and his end. Since difficulties attend the reaching of most ends that are worth while, and since there is a natural tendency to become discouraged and to abandon activity when serious difficulties are met and activity becomes disagreeable, entire educational schemes have been built around the conception of effort, though generally not under that name, but under that of discipline. Such educational schemes have frequently involved one or both of the following errors: (1) In the first place, it is overlooked that all normal effort involves an end, a good, or something satisfactory, for the sake of which activity occurs. This end for the sake of which activity occurs is of interest to the agent; or it represents an interest (as we talk of a man's business interests or concerns), something of importance, of value to him on its own account. Thus effort and interest (*q.v.*) are not normally opposed to each other, but are correlative. That is, the greater the interest in the end, the greater the desire for it, the more effort is the person willing to put forth in achieving it; while what seems of little account or worth is, for that very reason, not worth enduring much pains or trouble to reach. This statement does not imply that the end of activity is pleasure, or getting agreeable sensations; but it does imply that every genuine end is agreeable or of interest in the very fact of being an end. Effort, pain, trouble, struggle, is concerned not with the end, but with the means of attaining the end. The educational fallacy consists in ignoring the primary place belonging to an end having value on its own account, and supposing either that disciplinary effort can take place without any end in view, or else that one result is just as good as another, being but an excuse in any case for seeming willingness to undergo painful toil. (2) In the second place, it is thought that since effort in behalf of ends, in spite of difficulties, is a necessary trait of character, power of effort

may best be secured by multiplying difficult tasks, introducing obstacles, making work disagreeable, and then compelling pupils to keep at work, in spite of their natural reluctance. This introduction of difficulties, obstacles for their own sake, has, however, no relation to surmounting obstacles that lie in the way of achieving an end. When there are so many ends intrinsically valuable whose attainment is attended with difficulties, there is no need to invent difficulties or create tasks merely for the sake of calling out effort and securing discipline.

There are of course many ends that are important and valuable whose worth is not immediately recognized. In their case it is, of course, a genuine educational problem to bring the young to such a recognition of their value as will stimulate to effort for their realization. But the nature of this problem is entirely misconceived when it is taken to be a matter not of leading pupils to appreciate new values, but of doing disagreeable things without any appreciation of any end. Since the latter is a psychological impossibility, when it is attempted, the effect upon the pupil is (1) to lead to evasion, shirking, procrastination; or (2) to keeping the mind upon something else which is agreeable, and doing the task with a minimum of attention and thought, in a routine, perfunctory way (one of the chief methods of inducing habits of mind wandering in pupils); or (3) fastening upon some trivial, external, or irrelevant phase of the activity as a source of interest and making that the end which carries the disagreeable means. It is, unfortunately, only too true that a skillful teacher can "arouse an interest" in performing even the most mechanical and unintelligent tasks; but if the same skill were used in leading children to appreciate the value of new ends that are intrinsically significant, so as to put forth effort, painful in itself, for the sake of realizing the valued end, a training of power in effort would be secured without the evils mentioned above, and also of a sort which would be available in the concrete situations of later life, while the training had in performing meaningless and trivial tasks is not available, to any extent, for transfer. DEWEY, J. *Interest as related to Will.* (Bloomington, Ill., 1896.)

**EGBERT, or EGBEHRT.**—Archbishop of York (735–766) and master of the York School. In the life of Egbert, as given in the *Dictionaries of Christian Biography* and *National Biography*, he is wrongly reputed as the founder of the famous York School and the teacher there of Alcuin, its famous master. But these lives are based on an anonymous and superstitious life of Alcuin, in a "very ancient Ms. at Rheims," existing in 1617 and never seen since. This Ms. was alleged to date from 829.

It pretended to be derived from information supplied by Sigulf, one of his pupils. But the date assigned to it is highly improbable, and the life is so mere a piece of hagiography, written for reading in church or refectory, being full of miracles interspersed with pious reflections, as usual in the lessons for saints' days, that it cannot be accepted as of good historical authority. This anonymous French legend writer not only makes Heberet, as he calls him, Alcuin's master, but by way of asserting the tradition turns Egbert himself into a pupil of Bede's and a monk from boyhood and makes Bede live twenty years longer than he did. It is impossible, if Bede had been Egbert's master, that Bede would not himself have referred to this fact in the famous letter of advice which he wrote to Egbert on his becoming archbishop (Bede's *Ecclesiastical History*, ed. Plummer, i. 405), in which he pointedly refers to having stayed with him as a guest and discussed all sorts of political and religious questions with him as a justification for addressing his friend and equal, now become his father in God, in the somewhat puritanical strain he adopts. Had Bede ever held to Egbert the relation of master to pupil, a reference to this would have been a much more direct and effective apology, if indeed any apology at all would be needed. However, the legend writer tells how Heberet followed in Bede's steps as a teacher. "For from dawn, if there was no obstacle and it was not a saint's day, to the sixth or very often till the ninth hour, sitting on his bed, he opened the secrets of scripture to his pupils as was appropriate to each. Then he got up and said his prayers and mass. And then again towards vespers, when except in Lent, he took a spare but well-cooked meal with his pupils, he did not spare the tongue of the reader, so that he might be refreshed with bread in both kinds. Afterwards you might see the boys in the father's presence, piercing each other with their sharpened weapons, discussing in private what afterwards they would in serried ranks fight in public." This is a picture not of a public school such as that which a busy bishop might have held at York, and Alcuin in the palace school at Aachen, where grammar and literature and logic were taught, but of the aged abbot in the retired leisure of the monastery with a few of the younger brethren learning theology. The picture is inconsistent with a later passage, depicting a real public boarding school, which seems to have been taken from Alcuin's own poem, but transferred from Albert to Egbert, — with whom and Eanbald, Albert's successor, the *Dictionary of Christian Biography* confuses him: "He had indeed a crowd of scholars, noblemen's sons, some of whom were taught and instructed in the rudiments of the art of grammar, others in the discipline of the liberal arts, and some in holy scripture." That Egbert did indeed teach school at York is not to be

doubted, since Alcuin himself says so. But neither Alcuin nor Alcuin's biographer represents Egbert as creating or founding the school, any more than Bede represents Theodore and Adrian as founding Canterbury School. Just as Canterbury School must be attributed to Augustine, so York School must be attributed to Paulinus, its first bishop. Indeed, Bede directly bears witness to this by telling us how the song school continued under James the deacon, who stayed in the North during the reaction to paganism which followed on Edwin's death, when Paulinus fled. The cathedral remained, and on Wilfred's coming as bishop in 664, James collected a school of singers round him, while Wilfred himself no doubt taught the grammar school, which then included all learning.

Of Egbert Alcuin simply says that "Wilfred II handed over (in 732) to Egbert the rights of the venerable see when he caused him to be his successor. He was of royal blood and was a most illustrious ruler of this church and an admirable teacher (*egregius doctor*) and ruled for thirty-four years." This matter-of-fact sort of way of speaking of Egbert's teaching entirely negatives any idea of his having founded the school or of his being Alcuin's master, and is in striking contrast to the way Alcuin speaks of Albert (*q.v.*). The school is treated as a going concern, taught by the archbishop as a matter of course.

**EGO**—This word has long been used in technical writing as synonymous with the word "self" (*q.v.*). It has been used to distinguish the essence of conscious personality from the physical world or the non-ego. The derivatives of the term are used in popular parlance. The word itself is used for the most part only in technical literature.

C. H. J.

**EGYPT, EDUCATION IN.—Ancient Egypt.**—The Egyptian culture was the product of the Nile Valley. Until very recently our knowledge of Egyptian history reached back only as far as the age of the builders of the great pyramids, and Menes, the traditional founder of the first dynasty, had come to be regarded as mythical. But the pyramids presupposed a high stage of civilization, and the question of its origin was soon raised. A widely accepted theory, and one still held by a number of

scholars, regards Egyptian culture as Babylonian in origin. The recent excavations have, however, disproved this claim. We are now able to trace the development of Egyptian culture from its beginnings in the neolithic, even the paleolithic age. By 4241 B.C. astronomical knowledge had developed to such an extent among the inhabitants of the Delta that they were able to introduce a calendar with a year of 365 days. A millennium later Babylonian civilization was still in its beginnings.

The old adage that necessity is the mother of invention is perhaps nowhere better exemplified than in Egypt. Egypt's earliest inhabitants, pushing in from the edge of the desert, found in the alluvial valley of the Nile one of the most fertile areas on the face of the earth. But even after they had subdued the jungle, they were compelled to keep up a continuous struggle with nature, for Egypt is practically rainless, and it is only by making use of the water of the Nile that the soil, ever replenished by the silt deposited by the yearly inundation, is made to yield the abundant returns of which it is capable. The Egyptians early developed an extensive system of irrigation, and were thus able to produce an agricultural wealth sufficient to maintain a population far greater in density than is found anywhere in Europe to-day. This agricultural wealth was the foundation upon which Egyptian culture was built. Egypt has been called the mother of the mechanical arts, and the reason is not hard to find. In Egypt man's ingenuity is taxed to the utmost to devise ways and means for making the best use of his natural assets. Perhaps this explains why it was that the Egyptians never pursued knowledge for its own sake, never cared for the theoretical. Egyptian education remained in all periods intensely practical. One of Egypt's wise men is represented as admonishing his son as follows: "Give thy heart to learning and love her like a mother, for there is nothing that is so precious as learning." He goes on, "Behold, there is no profession which is not governed. It is only the learned man who rules himself."<sup>1</sup> It was because learning gave a man superiority over the unlettered that the Egyptian pursued her so diligently. Learning opened the way to official preferment, while the ignorant man, "whose name was unknown," was "like the heavily laden donkey" and was "driven by the scribe." These scribes, that is, officials, never weary of telling of the superiority of their profession over all others, and not infrequently boast in their tomb inscriptions of how, by their ability, they were able to rise from obscurity to positions of honor at the court.

The Egyptian boy spent the first four years of his life, the years of childhood, with his toys.

<sup>1</sup> Unless otherwise indicated, quotations are from *Erman's Life in Ancient Egypt*.

Many of these are preserved in our museums, such as a crocodile with movable jaw, dolls with movable arms, a jointed doll representing a slave grinding corn, etc. Theoretically the father was supposed to look after the education of his son, as is shown by the many dialogues of the didactic literature between father and son. But in practice the boy was sent away to school. In the Old Kingdom all of Egyptian life centered about the absolute monarch and his court. Consequently the boys of the wealthy were sent to the schools attached to the palace, where they were educated with the king's sons. The tutor of the princes, who was called their "nurse," was one of the highest officials of the court. A man who later became high priest was brought up by King Menkure "among the royal children in the great house of the king, in the room and dwelling place of the king." This Pharaoh's successor contended to show him favor, and when he had reached the age of manhood gave him "the great royal daughter Ma'atkha to wife." So in the time of the Middle Kingdom a nomarch of Siut relates with pride how he had taken his swimming lessons with the royal children. Another says, "His Majesty seated me at his feet in my youth, and preferred me to all my companions. His Majesty was pleased to grant me daily food, and when I walked with him, praised me each day more than he had the day before." He, too, was given a daughter of the king in marriage. Under the Empire the schools seem to have been attached to the various departments of the government where instruction was given by one of the higher officials to whom the pupils were assigned and under whom they served a sort of apprenticeship. One of these pupils writes to his master, "I was with thee since I was brought up as a child; thou didst beat my back and thy instructions went into my ears." There must have been a large number of these "instruction houses," as the schools were called, to train the vast army of officials who looked after the affairs of the government. The ranks of the officials were recruited largely from the middle class.

Discipline was severe, and there was plenty of flogging. The Egyptians held that by this means they were able to train all animals. "The youth has a back, he attends when it is beaten." "Spend not thy day in idleness, or thou wilt be flogged. For the ears of the young are placed on the back, and he hears when he is flogged." With such precepts as these continually put into practice, it is no wonder that we are told that the children left school, when the noon hour was announced, "shouting for joy." The master saw to it that the boys did not oversleep themselves, thus missing part of lesson time, the results of which, they were taught, "endured forever like the mountains." The boys were sparingly fed: three rolls of bread and two jugs of beer brought daily from home by the

mothers constituted the scant fare upon which they had to subsist while they learned their lessons, consisting largely of "instructions" or precepts, among which were such as "Be not greedy to fill thy body," "Share thy bread with others." The boys probably looked upon this severity as a matter of course; their revenge came when they in turn had become masters and flogged their pupils, or when, as official scribes, they had the pleasure of seeing their deputies hale the taxpayers before them while they made the inventories of the assessable property, the probable value of which was usually ascertained only after the administration of sound beatings.

Education in Ancient Egypt consisted largely in the inculcation of ethical precepts, practical philosophy, and good manners. The boys also received instruction in gymnastics and swimming. After they had mastered the art of writing, which must have been an exceedingly laborious task, they were set to work at copying "instructions." One of the oldest examples of the didactic school literature is the *Papyrus Prisse*, dating from the beginning of the Middle Kingdom, but containing the wisdom of Kagemni and Ptah-hotep, viziers respectively of Snefru of the Fourth, and Isesi of the Fifth Dynasty. Among the sayings of this book are the following: "Be not proud of thine own learning, but do thou take counsel with all men, for it is possible to learn from all. Treat a venerable wise man with respect, but correct thine equal when he maintains a wrong opinion. . . . Calumnies should never be repeated. . . . In a strange house look not at the women; marry; give food to thy household; let there be no quarreling about the distribution." Even more detailed is the advice of the instruction dating from the Empire. "Let thine eye be open, lest thou become a beggar, for the man that is idle cometh not to honor. . . . Enter not uninvited into the house of another; if he bids thee enter, thou art honored. Look not around in the house of another. If thine eyes see anything, be silent about it. . . . A man's ruin lies in his tongue. . . . Do not sit down while another stands who is older than thou or who holds a higher office than thine."

But there were other forms of literature which the boys copied and studied. A favorite for almost a thousand years was the story of Sinuhe, written in the Middle Kingdom and telling of the adventures of this nobleman, who, doubtless for political reasons, was compelled to flee the country on the accession of Sesostris I (1980-1935 B.C.), and who, after spending a long time in Syria, was pardoned in his old age by the Pharaoh and allowed to return home.

The time of the Middle Kingdom was the classical age of Egyptian literature. Besides the story of Sinuhe, we have an account of the adventures of the prototype of Sinbad the Sailor (Breasted, *History of Egypt*, p. 203). Fairy tales circulated among the common people, and found expression in literary form

(*Papyrus uestcar*). Events of everyday life were made the subjects of "fine writing," which had now become popular. "*The Tale of the Eloquent Peasant* was composed solely in order to place in the mouth of a marvelous peasant a series of speeches in which he pleads his case against an official who had wronged him, with such eloquence that he is at last brought into the presence of the Pharaoh himself, that the monarch may enjoy the beauty of the honeyed rhetoric which flows from his lips" (Breasted, *op. cit.*, p. 204). This age also developed philosophical works. One of the Berlin papyri (No. 3024) represents an unfortunate, weary of life, arguing with his soul on the advisability of ending their unhappy existence. The opposite extreme is shown in the *Song of the Harper*, which dwells upon the transitory nature of life but advises the fullest enjoyment of it while one may (Breasted, *op. cit.*, p. 206). Professor Erman calls it the national drinking song of the Egyptians. The poetry of this period ranges from simple compositions, such as the *Song of the Threshers*, to hymns singing the praises of the reigning monarch, and showing rigid strophic structure, as *The Hymn to Sesostris III* (Breasted, *op. cit.*, p. 207).

The favorite mode of instruction in the time of the Empire was by means of epistolary correspondence between tutor and pupils in which the former imparted wisdom to the latter and taught him the proper forms of letter writing. A large number of these exercises have come down to us. They are easily recognized by the corrections written by the tutor in the margins. On the back of these letters are frequently found jottings referring to the work in which the pupils were engaged while pursuing their studies; another evidence of the practical nature of Egyptian education, and reminding one of the famous spelling lesson in *Nicholas Nickleby*.

The study of literature was but the means to an end. Thereby facility in writing was acquired and the correct forms and usages of the language mastered. As already indicated, many persons of obscure origin were advanced to high official positions because of the exceptional ability which they showed, but the large majority of scribes remained clerks and secretaries, or overseers of lower or higher rank. The mastery of business and legal forms—bills and accounts, receipts, contracts, wills, deeds, etc.—took up the greater part of the pupils' time. A large number of such legal and business papyri dating from the Old Kingdom were found on the island of Elephantine, and are now preserved in the Berlin Museum.

An interesting papyrus dating from the Middle Kingdom shows the practical nature of the mathematics of the Egyptians. This document contains rules for measuring fields, determining the capacity of a granary, etc. The Egyptian did not have division as we know it. Instead of dividing, he kept multiplying the

divisor until he got the dividend. With the exception of  $\frac{2}{3}$ , the only fractions they could handle were those with 1 as numerator. Their rule for determining the area of a circle is worth mentioning. The diameter was taken, one ninth of it subtracted therefrom, and the result squared. The Egyptians studied the heavens. They made charts of the constellations, and by means of extensive tables could determine with considerable accuracy the position of many of them. As we have already seen, their practical knowledge of astronomy had enabled them to introduce a calendar, based upon the heliacal rising of Sirius (Sothis) as early as 4241 B.C., but they never developed any theory of the heavens similar to the Babylonian astrology to be handed down to later times as the highest wisdom.

Medicine was extensively studied and practiced in Egypt. "The medicaments recommended comprise nearly everything which can in some way or other be swallowed, whether in solid, mucilaginous, or liquid form" (Maspero, *Dawn of Civilization*, p. 219). Many of the recipes of Egyptian physicians were borrowed by the Greeks, and one, for determining the sex of an unborn child, found its way into the folk medicine of modern Europe (Paullini, *Neuercmchrter heilsamer Dreckapotheke* (1697), see Erman, *Agyptische Chrestomathie*, p. 48). If it is remembered that it was only with the rise of modern science that hocus-pocus was banished from our own medicine, it will not cause surprise to learn that magic always played the most important rôle in that of the Egyptians.

One must visit the museums of Europe and Egypt to gain an adequate conception of the marvelous technical skill developed by the Egyptians in the carving of wood and ivory, in metal working, in sculpture and painting. Back of the skill of the artisan was the mind of the artist-designer, one of whom, an "overseer" of the "gold house" where the "figures and images of all the gods" were fashioned, tells how he gained the royal favor, and was finally made counselor of the treasury (Breasted, *op. cit.*, p. 245). But the ripest genius of Egyptian culture found expression in architecture. The temples of Egypt have held the admiration of the Greek, the Roman, and the modern world; they are being studied by all students of architecture to-day. The Egyptian architect was a man possessed of all the learning of his day. The first of these of whom we have any record was the wise man Imhotep, learned in priestly wisdom, magic, medicine, and architecture. He was the patron saint of all the later scribes, and "2500 years after his death he had become a god of medicine, in whom the Greeks, who called him Imouthes, recognized their own Asklepios" (Breasted, *op. cit.*, p. 113). In the Old Kingdom the prime minister frequently held the office of chief architect, a thing not unknown in the following periods. To the

genius of Ineni, Senmut, Thutiy, Hapuseneb, and others, the architects and favorites of the Pharaohs of the Eighteenth Dynasty, we owe the magnificent buildings of the capital of the Empire.

Finally, a word about the impression the Egyptian learning made upon the Greeks. It was during the restoration of the Twenty-sixth Dynasty that the priests, who were now the only ones who could read them, collected and studied the writings of the past, now regarded as sacred, and read into them meanings which they never possessed. The Greeks accepted these fanciful interpretations all the more readily because of the awe inspired in them by the impressive remains of the material civilization of the Egyptians with which they had become acquainted. Their opinion of the marvelous wisdom of the Egyptians was handed down to modern times and was only shown to be false by the decipherment of the hieroglyph during the last century.

D. D. L.

NOTE. — Non-Egyptologists are apt to be confused by the widely divergent systems of chronology found in the different histories of Egypt. This is not the place to discuss this problem; suffice it to say that, in the opinion of the writer, Meyer in his *Ägyptische Chronologie* has said the final word on the subject. The dates here appended for reference are taken from Breasted, *A History of Egypt*, pp. 597 f.

**Modern Egypt.** — Modern education in Egypt is the product of two agencies: the missionary, and the European powers that have had control of the political affairs of the country. The population is mixed as regards racial origins and religious beliefs, but the vast majority of the people, 91.8 per cent, or a total of 11,207,359, are Moslems; Christians, adherents of the Coptic and Greek churches, form 7.8 per cent; Jews .34 per cent. Apart from the necessity of raising an annual tribute for the Sultan's treasury, the Khedive is supreme in Egypt, save for the authority exercised by the English adviser, whose sanction is required for every financial act of the government. This authority was conferred by the Khedive in 1883, at which time the system of two controllers-general, one English, the other French,

which had been adopted in 1879 by agreement of the European powers, was discontinued. Down to 1883 French influence predominated in the system of modern education; since that year, it has given way to the English influence.

The existing provision for education in Egypt consists of native schools, many of which have a very ancient history, and modern schools. Efforts have recently been made to obtain a complete survey of schools and higher institutions and to bring the elementary schools, both native and foreign, under a measure of government supervision. As a consequence, the educational statistics of Egypt, in regard to system and completeness, compare very favorably with those of the most advanced European nations. In the reports on the subject issued annually by the director of the statistical department, the schools are classified under the following heads: (1) government schools; (2) government kuttabs (vernacular elementary schools); (3) kuttabs under government inspection; (4) other Egyptian schools; (5) foreign schools.

The government schools owe their origin to Mohammed Ali Pasha, who was appointed governor of Egypt in 1806, and made himself master of the country by force of arms in 1811. In 1841 Mohammed Ali was recognized as Viceroy under the guarantee of the five great European powers. Convinced of the superior value of Western education as compared with the system of his own country, this ambitious ruler established schools modeled on those of Europe for the purpose of training Egyptian students for careers in the different branches of the public service. In the last decade these schools have increased in number, and at the present time they form a system, including primary and secondary schools, colleges, and technical institutions, in all of which instruction is given partly through the medium of a European language. Formerly an English side and a French side were both included in the government schools; but within the last few years the number of pupils in the latter has been steadily decreasing, and in many cases the French division has been discontinued. When first established, the government schools were not only free, but the students were boarded and clothed at public expense; under Ismail Pasha (1863-1879), the fourth Khedive in direct descent from Mohammed Ali, students received money allowance from the government. This gratuity ceased, however, in 1874, since which time fees have been charged.

The foreign schools are also modern, and are either missionary schools or are maintained by European governments in the interests of their own people in Egypt. The schools which are classified as Egyptian are Moslem schools, or schools pertaining to the native Christian churches, *i.e.* Greek and Coptic. The language of instruction in these schools is generally Arabic, and the teaching is mainly directed to religion.

EGYPT

The number of pupils enrolled in all classes of schools at the date of the last report (1908) was 288,445 (249,226 males; 30,719 females). Of the total number, 175,515 attended the kuttabs. The following table shows the distribution of the remaining 113,430 pupils.

NATIONALITY	SCHOOLS	TEACHERS	PUPILS
Egyptian . . . . .	326	3,147	66,049
English . . . . .	25	153	2,287
American . . . . .	156	410	12,640
Austrian . . . . .	10	68	1,647
Dutch . . . . .	2	7	159
French . . . . .	137	1,185	17,805
German . . . . .	5	60	822
Greek . . . . .	32	151	5,774
Italian . . . . .	40	267	5,766
Other . . . . .	2	24	481
Total . . . . .	735	5,475	113,430

Very nearly half the above schools, 336, and more than half the pupils, 68,378, were reported from Cairo, Alexandria, and the three canal towns, Port Saïd, Ismailia, and Suez. The modern schools maintained by the Egyptian government in 1908 were as follows:—

SCHOOLS		NUMBER OF STUDENTS	
Class	Number	Egyptians	Foreigners
Primary . . . . .	38	8,481	75
Secondary . . . . .	4	1,897	12
Teachers' Training . . . . .	10	867	2
Technical and Special . . . . .	10	1,572	55
Higher . . . . .	5	665	4
Total . . . . .	67	13,842	148

The higher schools include the following:—

DESIGNATION OF SCHOOL	NUMBER OF STUDENTS
Law . . . . .	390
Medicine . . . . .	155
Cadets (Magistrates) . . . . .	14
Engineering . . . . .	102
Chemistry . . . . .	4

In addition to the government schools, the French maintain at Cairo one higher school for young men, which in 1908 had 295 students. The American schools comprised in the table showing nationality are in charge of the American Mission, and are chiefly primary, but this organization maintains a college for girls at Cairo which has generally between sixty and seventy students. The remaining higher institutions are native, following the traditions, doctrines, and methods of the various religious sects. The largest and most important of these is the University at Cairo, El-Gama el Azhar University, with 9940 students and 329

EGYPT

teachers. This is the oldest institution in Egypt, founded in 972, and one of six higher institutions having a total of 15,000 students maintained by the Waqfs administration, or religious endowments pertaining to the mosques. Beside the six higher institutions, the Waqfs administration maintains thirty-one primary schools, with nearly 2000 pupils.

One of the most important efforts on the part of the Egyptian government in respect to education is the maintenance of day and evening technical schools. The foreign authorities have also engaged largely in this work. Altogether there were in 1908 four technical evening schools maintained by the government at Cairo, and six foreign evening schools of the same class distributed between Cairo, Alexandria, and the canal ports. These schools enrolled 912 students, of whom 273 were natives. There were also the same year 12 day technical schools with 726 students. There are several flourishing commercial schools in charge of French clerical orders.

From time immemorial indigenous schools, kuttabs, have been scattered throughout Egypt; some are attached to mosques, others are maintained by pious trusts, and some are purely private. It was not until 1897 that an endeavor was made to bring these rudimentary schools within the sphere of departmental supervision. Following English precedents, this was done by a system of inspection and awards of which the schools might avail themselves. Government aid was made dependent in each case upon daily instruction in the three elementary subjects, apart from any religious teaching, combined with the report of the government inspector as to the general condition of the school. The growth of the system is shown by the following statistics:—

YEAR	NO OF PRIVATE KUTTABS INSPECTED	NO OF PUPILS			NO KUTTABS SECURING GRANTS	TOTAL GRANT
		Boys	Girls	Total		
1898	301	6,938	598	7,536	110	82,475
1909	3581	174,023	16,852	190,875	3054	12,395

A staff of three inspectors and thirty-six sub-inspectors, several of whom are English, is maintained by the Ministry of Education in the exclusive interest of this work. There are also 143 kuttabs under the immediate control of the ministry, with about 1200 pupils. This brings the total number of pupils in supervised kuttabs to 202,000. While the instruction is given in the vernacular tongues, the endeavor is made to use modern methods, and, as far as the limited scope of the schools permits, to impart modern ideas.

In the statistical reports the schools are arranged under the different local divisions, namely: the five governorships (*mohafzas*)

of principal towns, and the fifteen provinces (*mudiriats*), which are subdivided into districts (*kisms*). From this presentation it is seen that while the modern schools are confined almost exclusively to the towns, the inspected kuttabs are increasing in the provinces and even in the remoter districts. The government maintains four training colleges, three for men and one for women, to prepare teachers for the kuttabs, and also weekly classes at thirty centers for the benefit of teachers already engaged in schools of this class. The expenditure for the vernacular schools rose from \$14,820 in 1898 to \$348,650 in 1908. The total expenditure for education by the ministry in the latter year was \$2,225,000.

**EIGHTEENTH-CENTURY EDUCATION IN ENGLAND.**—Broadly speaking, it may be said that the whole of the eighteenth century was a period of preparation for the great activities in all branches of education that began to operate at the opening of the nineteenth century. From the beginning till near the end of the eighteenth century there was on the one hand a process of declining administrative and teaching efficiency in all branches and grades of education and on the other the sowing of seeds that were destined to produce enormous

harvests. Thus elementary education, as represented by small endowed schools, charity schools, and workhouse schools, grew less and less efficient, but in fact we find in the early part of the century a great multiplication in the number of those schools, and in the latter part of the century they were supplemented by Sunday schools and at the very end by monitorial schools. Again the numerous endowed grammar schools were fairly efficient during the first quarter of the century, but after that date a steady decay set in that no effort seemed able to stop. By 1750 the grammar schools, except in very special cases in growing towns or famous centers of learning, were becoming less and less efficient, and the attendance smaller and smaller. The masterships and even the usherships became in numbers of cases sinecures, and the endowments of the schools were shamelessly abused. The Court of Chancery (*q.v.*) and the Commissioners of Charitable Uses created by Queen Elizabeth made efforts to check the disease, but the system of appeals and the terrible cost of the proceedings made little progress possible. Certain great ecclesiastics, such as Dr. Markham, Archbishop of York, at one time the Headmaster of Westminster School, did something to improve matters, but the position as stated by Lord Kenyon, Chief Justice, in 1795 shows how complete was the failure of secondary education at that date: "Whoever will examine the state of the grammar schools in different parts of this kingdom will see to what a lamentable condition most of them are reduced, and would wish that those who have any superintendence or control over them had been as circumspect as the Archbishop of York has been on the present occasion. If other persons had equally done their duty, we should not find, as is now the case, empty walls without scholars, and everything neglected but the receipt of the salaries and emoluments. In some instances that have lately come within my own knowledge, there was not a single scholar in the schools though there were very large endowments to them" (*The King vs. the Archbishop of York. Term Reports,* vol. VI, p. 490). On the other hand, the schools that remained efficient, such as Eton (*q.v.*), preserved a very high standard of classical scholarship, and this standard was likewise maintained at the universities. Moreover in an age of change the schools were in fact preserved intact; their endowments were not lost or turned to other and lower uses. The vast secondary system was preserved, and is to-day at last reaching a remarkable degree of efficiency. In the universities, too, the teaching efficiency steadily declined until the first, the Oriel, revival at Oxford toward the end of the century. Adam Smith, writing in 1776, says, "In the University of Oxford, the greater part of the public professors have for these many years given up altogether even the pretence of teaching." Things were as bad at Cambridge.

Yet in this period we find at both universities that the mighty classical tradition was preserved intact, and famous lecturers, such as Blackstone at Oxford, still lectured. Richard Porson (*q.v.*) (1759-1808), perhaps the greatest of all English scholars, was educated at Eton, adorned Oxford and Europe in this period, and produced a new text of Euripides, while both universities produced scholars and authors of the highest gifts. Moreover, it was in 1747-1748 that the Cambridge Mathematical Tripos was founded at Cambridge, and no less than twelve Cambridge professorships were founded in the eighteenth century. Both universities were saved for their great work of the nineteenth century, work of light and leading for the entire western world. The eighteenth century was a period in English education for which it is difficult to account.

**EINHARD, or EGINHARD** (c. 770-840). — Biographer of Charlemagne and a leading classical scholar of the early Middle Ages. After receiving his early education at Fulda, Einhard was sent to the school of Alcuin (*q.v.*), where his ability in mathematics and architecture attracted attention. He was appointed private secretary, and was also given the supervision of buildings, including the cathedral and palace at Aachen. He was also sent on diplomatic missions by the Emperor. He continued to enjoy royal favor after the death of Charlemagne, and was given several abbeys and fiefs by Louis the Pious. He himself founded a monastery at Mühlheim, which he named Seligenstadt. His influence was exercised mainly in Belgium, where most of his abbeys lay. He corresponded with the best classical scholars of his day, among them being Servatus Lupus of Ferrière. His best known work is the excellently written *Vita Caroli Magni*, which is frankly an imitation of Suetonius' *Vita Augusti*. His interest in architecture led to the study of the work of Vitruvius. His other works, which show evidence of wide classical reading, include *Translatio et Miracula SS. Marcellini et Petri*, and *Epistola*. In one of his letters to his son he expresses his belief that the young must be disciplined to walk in the ways of righteous-

ness, that insight and morality go together, but that knowledge without humility leads to nothing but arrogance.

**EISELEN, ERNST WILHELM BERNHARD** (1792-1846). — One of pioneers of gymnastic instruction in Germany. Born in Berlin, he attended the Graue Kloster Gymnasium, and became a favorite disciple of Jahn (*q.v.*). Being unable on account of his poor health to take part in the Wars of Liberation, he took charge of Jahn's open-air gymnasium in the Hasenheide, near Berlin, until 1820, when gymnastics fell under the official ban in Prussia. During the time of Jahn's imprisonment he continued to work for the cause of gymnastics, and in 1827 he succeeded in obtaining the permission of the authorities to open a private gymnasium, which, at that time, was almost the only training school for teachers of physical training in Germany. With Jahn, Eiselen published in 1816 the *Deutsche Turnkunst.* F. M.

**EITELBERGER, RUDOLF** (1817-1885). —

A prominent representative of industrial and art education in Austria; was born in Vienna. In 1852 he became professor of the history of art in the University of Vienna. On the model of the Kensington Museum, he founded the Austrian Museum of Art and Industry in Vienna, which he directed until his death. This institution, one of the best of its kind, has exerted a great influence on art-artisanship throughout Austria. Through the efforts of Eitelberger the methods of art teaching in the industrial and other schools of Austria were greatly reformed. F. M.

**ELABORATION.** — A form of exercise used in the teaching of English composition. The student is given a few suggestive words or phrases, or an analytical outline, and told to extend it into an essay, description, or narrative. H. S.

See LANGUAGE, ENGLISH, TEACHING OF; COMPOSITION.

**ELDON, LORD, AND EDUCATION.** — The influence of Lord Eldon, the famous Lord Chancellor and brother of the great international jurist, Lord Stowell, on English education through his decisions was a retarding, but probably on the whole, a good influence. He set his face firmly and successfully against the attempt

made at the beginning of the nineteenth century to convert derelict secondary or grammar schools into primary schools. His decisions seemed hard at the time, but his policy was a right one, for the country could not afford to lose in the long run a single grammar or secondary foundation. Lord Eldon, however, in the strictness of his construction of educational trusts, went too far. On July 22, 1805, he held in the case of *Attorney-General vs. Whiteley* (Vesey's *Chancery Reports*, Vol. XI, p. 241) that the foundation in question being a free grammar school at Leeds for teaching grammatically the learned languages, the Court was bound to refuse to permit the allocation of part of the funds to procure masters for French and German, or to create a subsidiary establishment with a view to commercial teaching. But in the case of *Attorney-General vs. Earl of Mansfield*, decided many years later (1826-1827), Lord Eldon held that where a school ought to be a grammar school for instruction in the classics, the trustees would not be permitted to convert it into a school for teaching merely English writing and arithmetic, even though it had ceased before the time of living memory to be a place for classical instruction, and though it appeared from old regulations that elementary instruction in English had always been one of the subjects of the school. Lord Eldon rightly declined to allow the character and scope of the school to be altered. To-day his conservative stand against a misapplication of the *cy-près* doctrine is a matter of thankfulness. After the date of these decisions the curriculum in grammar schools under the influence of Lord Lyndhurst became more elastic, but by that time it had become difficult to convert a grammar school into a school of a lower grade. It should be noticed that Lord Eldon in the House of Lords (Aug. 11, 1807) opposed Mr. Whitbread's Bill for the Education of the Poor. The Bill proposed that the poor children of each parish should be entitled to receive two years' education between the ages of seven and fourteen years, and provided machinery to render this possible. The Bill in its passage through the Commons was deprived of its compulsory character, and became merely adoptive, though still retaining the principle of raising the necessary money by means of rates. Lord Eldon opposed this bill when it reached the House of Lords, though he was in favor of improved educational conditions. The bill was in fact hardly a practical measure and was not likely to attract the support of the very practical Lord Chancellor.

**ELECTRICAL ENGINEERING.**—See TECHNICAL EDUCATION.

**ELEMENTARY MATHEMATICS.**—This is a term loosely used to designate either (1) the mathematics of the elementary school (*q.v.*), usually simple arithmetic and the mensuration of common figures, or (2) the mathematics preceding the theory vaguely styled "higher mathematics." As used in the second of these senses in the United States, the term usually includes simple commercial arithmetic, algebra through geometric progressions, plane and solid geometry, plane and spherical trigonometry, advanced algebra (usually with a little of the theory of equations), plane analytic geometry, and the elements of the differential and integral calculus. These subjects represent approximately the work of the elementary and secondary school, and of the first two years of the American college. D. E. S.

See ARITHMETIC; ALGEBRA; GEOMETRY.

**ELEMENTARY SCHOOL TEACHER.**—See JOURNALISM, EDUCATIONAL.

**ELEMENTARY SCHOOLS.**—A general term applied to the first eight years of the public school course of study. The term is now applied to all of the different grades above the kindergarten and below the high, or secondary school. It is a general and a comprehensive term, which has gradually come to supplant and to include the old terms of primary school, intermediate school, and grammar school. For greater convenience some school systems still subdivide their elementary school system into primary and grammar schools, and, in the North Atlantic group of states, the term "intermediate school" is frequently still retained to designate the upper primary and the lower grammar grades of the elementary school. E. P. C.

See ABECEDARIAN; GRAMMAR SCHOOLS; PETTY SCHOOLS; PUBLIC SCHOOLS.

**ELEMENTARY SCIENCE.**—See BOTANY; NATURE STUDY; SCIENCE; ZOOLOGY, etc.

**ELEMENTS OF CONSCIOUSNESS.**—Certain writers on psychology regard it as the chief business of this science to analyze complex conscious processes into their irreducible elements. Thus the perceptual experience of seeing an object can be resolved into sensations of color, muscle sensations, and memory elements from past experience. Skill in such analysis is regarded by some as the chief end of psychological training (Titchener). Educational discussions have often been built

upon the basis of such analyses, the contention being, as Pestalozzi held, that it is necessary to supply the elements of an experience in order that the experience itself may be developed. An extreme illustration of attention to elements of consciousness appears in the contention that training in the alphabetical elements of a word is the necessary preparation for the recognition of the word itself. In recent educational discussions there has been a tendency to emphasize not the elements of the process, but rather the synthetic combination of these elements in a single whole. The recognition of a word has been treated as a complex which contains elements, but which from the point of view of the teacher should not be treated so much as a series of elements as the complex organized whole. The distinction between purely analytical or structural treatment of mental processes and the functional consideration of these processes has been emphasized in recent writing.

**ELIOT, WILLIAM GREENLEAF** (1811-1887). — University president; graduated from Columbian University at Washington, 1831, and from the Harvard Divinity School, 1834. He was active in the establishment of the public school system of St. Louis (*q.v.*), and was chancellor of Washington University from 1872 to 1887. Author of *Early Religious Education* (1855), and other works.

W. S. M.

**ELIZABETH COLLEGE, CHARLOTTE, N.C.** — An institution for the liberal education of women, maintaining preparatory, collegiate, commercial, music, art, expression, and physical culture departments. Twelve points of high school work are required for entrance into the college, certificates of approved schools being also accepted. The A.B. degree is conferred. There is a teaching staff of twenty-three members.

**ELIZABETHAN PERIOD IN ENGLISH EDUCATION.** — Queen Elizabeth succeeded to the English throne on Nov. 17, 1558; her reign ended with her death on Mar. 24, 1603. No period of equal importance in the history of English education (if that education be taken as a connected whole) is to be found until the organized revival of national education during the second half of the nineteenth century. Though Henry VIII and his son Edward VI were both scholars and lovers of scholarship, and in various ways endeavored to aid and to make more efficient the university grade of education; though in the reign of Edward VI something was done toward preserving a certain proportion of the grammar schools that reckless legislation had overtaken; yet the net results of those two reigns was to leave the country without the educational machinery that existed at the opening of the sixteenth century. Elementary schools as well as grammar schools had disappeared, and the universities were not only inefficient, but were the resorts of the vicious and idle.

The loss through the dissolution of monasteries and charities was enormous, and it was the business of the reign of Queen Elizabeth to substitute new educational facilities. Parliament felt from the first that the losses had been intolerable. Sir Thomas Smith in 1548 introduced into the Commons a school bill. Thomas Williams, Speaker of the House of Commons, in 1563 said, "I dare say a hundred schools want in England, which before this time have been: and if in every school there had been but an hundred scholars, yet that had been ten thousand; so that now I doubt whether there be so many learned men in England, as the number wants of these scholars." Williams much

underestimated the loss of grammar schools, and two hundred at least had disappeared. Yet by the year 1581 the loss had been made up. Richard Muleaster, writing in that year, said, "We have no great cause to complain for number of schooles and founders. For during the time of her Majesties most fortunate raigne already, there hath been mo schooles erected, than all the rest be, that were before her time in the whole Realme. My meaning is not to have so many, but better appointed both for the maisters' entertainment and the commoditie of the places" (*The Positions*, p. 327). Indeed, an examination of the material shows that in Elizabeth's reign one hundred and eight grammar schools were founded and twenty-seven were additionally endowed, while forty nonclassical schools were founded and seven were additionally endowed.

Elizabethan legislation on the subject of education requires special notice. All repetition of the educational disasters caused by the dissolution of the monasteries and the chantries was prevented by an act in the first year of the Queen's reign (1 Eliz. c. 24) which dealt with certain monasteries and chantries, but which reserved (section 9) from annexation lands and property limited or appointed by any of the annexed corporations "to any Schole Master or to the finding of any Schole or Scolers to learning." Section 10 preserved from the operation of the act colleges and chantries in the universities or "any Chantry founded in any other place for the mayntenance of a Gramer Schoole or learning or where the Chantrye Preest is also appointed to teache children." An act of the same year (c. 22) enabled the Queen to make statutes, ordinances and rules for existing schools. But the Queen was also determined to secure the Protestant character of all schools and of the universities. The very first act of her reign (1 Eliz. c. 1, s. 12) made it necessary for every person taking a university degree to take the oath admitting the supremacy of the Crown in all matters spiritual and temporal. In the Royal Injunctions of 1559 (II, 40) the Ordinary was given the power to issue licenses to school teachers, and the Church followed this principle with assiduity. Convocation of the Province of Canterbury in 1571 laid down the rule that a license to teach was necessary, and added "that the Bishop shall approve no schoolmaster as worthy of the office of teacher, unless, in his judgment, he has sufficient knowledge" (*nisi quem suo judicio doctum invenerit*) "and unless he is recommended as worthy in life and morals by the testimony of pious men." (See also Archbishop Grindal's Injunctions [45] for the Province of York, 1571.) In 1580 the Privy Council ordered an inquisition into the religious opinions of all teachers and tutors, and from 1581 to 1588 special episcopal inquiries were made as to unlicensed teachers. Prosecutions for teaching without a license occurred. Thus on May 1, 1584, a

true bill was returned against William Smithers for keeping a common school in the Charterhouse without a license (*Middlesex Sessions Rolls*, Vol. I, p. 149). By statute in 1581 (23 Eliz. c. 1, s. 5) every schoolmaster had to be licensed and to attend church as provided by the act under a penalty of one year's imprisonment. These regulations and laws answered their immediate purpose, and in fact raised education to a high standard of efficiency, though a century later they led to a great and disastrous reaction. But in Elizabeth's time it was not only the religious, but the secular side of education that was enforced by the State. Almost immediately after the Queen's accession, a Royal Injunction was issued (II, Art. 39), which ordered that "every schoolmaster and teacher shall teach the grammar set forth by King Henry VIII of noble memory, and continued in the time of King Edward VI, and none other." The Church took up this lead. Archbishop Parker's *Articles of Visitation* of 1567 carefully inquired into the whole life of the grammar schools, and similar articles are found in succeeding years. Moreover, the Queen did not allow other necessary economic legislation to interfere with school attendance. The compulsory service of young persons contemplated by the Statute of Apprentices of 1562-1563 (5 Eliz. c. 4) was not to extend to "a Student or Scoler in any of the Universitees or in any Schoole." Every effort was made that the schools and the teachers should not be hampered. The schoolmasters, says Strype (in his *Annals of the Church under Queen Elizabeth*), were "commonly freed from taxes and ordinary payments, and had exemption from personal services commonly charged upon other subjects." No school or school property was charged with tithes or first fruits (1 Eliz. c. 4, s. 40 giving a general extension to the same provision created by 27 Hen. VIII, c. 42) for the universities and for Eton and Winchester. The act which confirmed the subsidies of the clergy (5 Eliz. c. 24) exempted the universities and every grammar school from the tax (s. 20). Moreover, schools were exempted from all aids granted to the Crown by Parliament from the time of Edward VI to 1763.

But these various provisions in aid of schools are slight as compared with the determined effort made by Queen Elizabeth to deal with the corruption and abuse of endowments that had steadily increased throughout the sixteenth century. The Reformation had destroyed innumerable endowments for education, but it had reformed few, and the universities themselves had, despite the danger that they ran, grown corrupt in the extreme. Henry VIII had attacked some of the university abuses vigorously in 1536 (28 Hen. VIII, c. 13), and positively forbade beneficed clergymen over the age of forty to remain in the university, and none under the age of forty who did not attend lectures. In 1571 Queen Elizabeth incor-

porated both Oxford and Cambridge in order to promote "the mayntenaunce of good and Godly literature, and the vertuose Education of youth within either of the same Universities." But the state of corruption continued, and William Harrison (1586) declared that it had become impossible for poor men's sons to win scholarships or fellowships. Bribery determined even the grammar school scholarships to the universities. Elizabeth had already dealt by an act of 1575-6 (18 Eliz. e. 6) with the financial position of the university colleges, and placed them upon a sound basis that made corrupt dealings with the rents of the college lands impossible; and now her heavy hand came down on the abuse of fellowships and scholarships. By an act of 1598-9 still in force (31 Eliz. e. 6) which recited that "the intent of the founders of Colledges Churches Collegiats, Churches Cathedral, Scoles, Hospitals, Halles and other like Societies within the Realm" to have "the fittest and most meet persons" elected to fellowships and scholarships without gift or reward had been neglected, and that the fittest persons were "sildome or not at all preferred . . . to the great prejudice of Learning and the Common Wealthe and Estate of the Realme"; the statute imposed forfeiture upon him "who taketh reward for his voice in such elections." The act was certainly effective, for in a few years the universities swarmed with students, and in 1612 there were nearly as many in residence as there are now. But the attack on corrupt practices did not cease with these measures. The endowments, as well as the use of the endowments, had to be protected, and in 1597 a statute confirmed and extended in 1601 (39 Eliz. e. 6 and 43 Eliz. e. 4) created a body called the Commissioners for Charitable Uses, which had power to inquire into abuses of charitable bequests or donations and to rectify the same by decree. By this body (which remained in existence as late as 1888) some thirty-three schools were reformed. The system of appeals under the act, however, sadly marred its efficiency in the period when its need again became urgent in the eighteenth century. It is interesting finally to note that in the reign of Queen Elizabeth the idea of education at the cost of local authorities came to life. In the year 1561 the overseers of the city of Westminster were paying for elementary teaching, and in 1586 paid a part of the expenses of John Creverne at Oxford. The history of rate aid in education dates from about this period. The importance of the Elizabethan period in the history of every branch of education can hardly be overestimated, though, strangely enough, it is only modern times that have reaped the full fruit of the seed then sown. **ELIZABETHTOWN COLLEGE, ELIZABETHTOWN, PA.** — A coeducational institution established in 1900 by the Church of the Brethren (German Baptist) of eastern Pennsylvania. Academic, pedagogical, commercial, industrial, music, and biblical departments are maintained. The institution does not grant degrees, but is affiliated with degree-granting colleges. There is a faculty of seventeen teachers.

**ELLIS, WILLIAM (1800-1881).** — Economist, founder of the Birkbeck schools, and advocate of systematic instruction in social economy. Descended from a French Huguenot family (named De Veizan), Ellis, in his fourteenth year, entered the office of his father, a marine underwriter in London. In 1820 he became acquainted with Jeremy Bentham (*q.v.*) and James Mill and formed an intimate friendship with John Stuart Mill (*q.v.*), of whose Utilitarian Society, founded in 1822, he was one of the first members. In 1824 he was appointed assistant manager of the Indemnity Mutual Marine Insurance Company, in the service of which (as chief underwriter, 1826-1876) he continued till his death. Throughout an arduous business career he devoted his leisure and a large part of his fortune to disinterested labor for school reform and to experiments in education. His main purpose was to give the course of instruction in elementary schools a direct bearing upon the pupils' future duties in life, with a view to the strengthening of personal character and to the creation of a higher ideal of citizenship. He therefore advocated the introduction into school curricula of systematic courses of moral instruction, connected with the teaching of physical science, but mainly resting upon the principles and applications of political and social economy. In furtherance of his purpose he (1) wrote a series of handbooks on social economy for teachers and for pupils of different ages; (2) himself gave, in elementary schools and in training classes for schoolmasters, courses of lessons in social economy and in civic duty; and (3) founded in London and largely maintained from his private resources a number of schools in which the moral and economic instruction followed the principles and methods enjoined by him.

Ellis's works were designed to inculcate "the three great duties of social life: First, to strive to be self-supporting and not to be a burden on society; second, to avoid making any

engagement, explicit or implied, for the due performance of which there is no reasonable prospect; third, to make use of all superior advantages, whether of knowledge, skill or wealth, so as to promote to the utmost the general happiness of mankind." As a teacher, Ellis had remarkable gifts, especially excelling in the Socratic method of questioning and in the lucid exposition of complex economic facts. Florence Nightingale, who attended one of his classes, wrote long afterwards that his was the best and most effective teaching she had ever heard, bringing the most difficult subjects in an absolutely clear and most living way to the understanding of a child. In 1846 he began to give lessons in social economy to the children in some British schools in Camberwell, London. For many years he devoted much of his leisure to giving instruction in social economics, both in schools and to classes of schoolmasters. In 1855, at the request of the Prince Consort, Ellis gave courses of instruction in social economy to the Princess Royal (afterwards the Empress Frederick of Germany), the Prince of Wales (afterwards King Edward VII), the Princess Alice (afterwards Grand Duchess of Hesse-Darmstadt), and Prince Alfred (Duke of Edinburgh). The lessons left a deep impression upon the pupils, especially upon the Empress Frederick. In 1859, under the auspices of the Science and Art Department, Ellis gave lectures at South Kensington upon the teaching of social economy as a branch of school education.

For many years Ellis was munificent in his contributions to the support of schools in which systematic instruction was given in social duty. In 1846 he liberally helped William Lovett, the leader of the moral force Chartists, to secure the equipment and a master for an elementary school in the National Hall, opened by the London Working Men's Association in Holborn, and for nine years continued the pecuniary aid without which the maintenance of that school would have been impossible. In 1848 he established (with the help of his trusted coadjutor, John Rüntz) a school for boys in the buildings of the Mechanics' Institution in Southampton Buildings, Chancery Lane (now known as the Birkbeck College, in Bream's Buildings). The Birkbeck School was so named in memory of the founder of mechanics' institutions, who had died in 1811. The first Birkbeck school was closed in 1873, owing to defects in the school buildings. But in the meantime many other schools on the same principle had been founded in different parts of London (viz. in Finsbury, Westminster, Bethnal Green, Peckham, Kingsland, and Gospel Oak), some by Ellis himself, and others by friends with his assistance. His purpose was to establish models in different districts of London in order to induce other school managers to adopt his methods of teaching.

Ellis stands out as a striking figure in the

educational history of mid-Victorian England. Throughout the absorbing duties of a life spent in commerce, in which he was eminently successful and highly respected, he kept undimmed the flame of intellectual passion which had been kindled in his early intercourse with the Benthamite circle. To him the laws governing human action and regulating social activities were not simply statements of scientific fact, but the revelation of moral truth. He himself found in them inspiration for right conduct, and desired to bring the knowledge of them not only to the mind, but to the heart of the nation. He had inherited the Calvinist passion for a clear intellectual interpretation of life. Social and economic science had for him the authority which his forefathers found in the Bible. He practiced with consistency the doctrines which he himself taught to others and wished to see incorporated in the course of study of every school. He denied himself the indulgences of wealth in order that he might spend largely, though unobtrusively, upon the furtherance of his educational ideals. The honesty of his thought and the thoroughness of his knowledge gave power to his teaching and weight to his advice. In spite, however, of the success of his schools and the acknowledged value of his instruction, his influence upon the educational practice of his time was limited, and his name comparatively obscure. This is partly explained by Ellis's uncoutness as a writer and by his misjudgment as to the finality of some of his economic presuppositions. But the record of his life and work points to a deeper cause of his relative failure. He was a pioneer of the movement for systematic moral and social instruction in elementary schools, and in this respect was before his time. But he lived through a period of confused transition in both the economic and political structure of English life. The old economic order from which he drew the materials of his instruction was slowly giving way to new conditions, not yet defined enough to furnish a firm foundation for the concise and clear-cut instruction which he regarded as indispensable for the elementary school. Ellis did not overstate the educational influence of systematic social instruction, but he overrated the certainty of some of the economic doctrines which he desired to inculcate. His educational theory presupposed a generally accepted social ideal. But he lived at a period in English history when no one social ideal commanded general acceptance. Consequently, courses of instruction which to his mind had an almost religious solemnity appeared to many of his contemporaries sterile or inadequate. For educational use, Ellis's thought was lacking in poetry and imagination. The intellectual and civic enthusiasm which, in his own case, supplied this defect were not always communicable by him, and still less by others, through the course of economic instruction which he planned. His greatness lay in his gift as a teacher, in his

intellectual sincerity, and in his self-denying passion for social welfare. M. E. S.

**ELLSWORTH COLLEGE, IOWA FALLS, IA.**—A coeducational institution, which received its present name in 1890 in honor of its principal donor. It maintains a college of liberal arts, school of education, school of commerce, conservatory of music, and schools of art and oratory. Students are admitted to the college on certificates from approved high schools and academies. The degrees of A.B., Ph.B., Sc.B., are conferred after the appropriate studies. There is a teaching staff of eighteen professors.

**ELMIRA COLLEGE, ELMIRA, N. Y.**—A college for the education of women founded in 1851 and located by charter in 1852 at Auburn as the Auburn Female University. The institution was transferred in 1853 to Elmira, and was chartered in 1855 as the Elmira Female College. The course of study from the first was made equivalent to that given in the best colleges for men. Admission is by certificate of the Regents of the University of the State of New York, the College Entrance Diploma of the State Education Department, and certificates from approved schools, or by examination, the requirements being fourteen units of high school work. The A.B. and B.S. degrees are given, the latter in household art, secretarial and finance and in music and literature as well as in the scientific course. The college has productive funds of \$200,000, and a total income, including tuitions, of \$60,000. The total number of students in 1909-1910 was 287. The faculty includes eighteen members.

**ELOCUTION.**—See **DEBATING; DECLAMATION; ORATORY.**

**ELON COLLEGE, ELON, N. C.**—A coeducational institution founded in 1888 by the General Convention of the Christian Church South, and opened in 1890. Preparatory, collegiate, commercial, and music and art departments are maintained. Candidates may enter by certificate from schools or by examination, the entrance requirements being equivalent to fourteen points of high school work. The degrees of Bachelor of Arts and Bachelor of Philosophy are conferred on completion of the appropriate courses. The faculty numbers fourteen.

**ELSTOB, ELIZABETH** (1683-1756).—The writer of the first English-Saxon (Anglo-Saxon) grammar; born at Newcastle-on-Tyne in 1683. Her mother died when Elizabeth was eight years of age. Eventually she accom-

panied her brother William, ten years her senior, to Oxford, where she pursued Anglo-Saxon studies, and was said to have good acquaintances with some other languages. She is said to have been "the first English woman that had ever attempted the Saxon language, a tongue ancient and obsolete." Her biographer adds "in all probability the last." In 1709 she published: *An English-Saxon Homily on the Birthday of St. Gregory: uncintly used in the English Saxon Church, giving an account of the conversion of the English from Paganism to Christianity. Translated into modern English with Notes, etc., by Elizabeth Elstob*. After this she was styled "the justly celebrated Saxon Oracle." In the Preface is a very incisively worded claim for the education of women, and she invites the ladies to be acquainted with the language of their predecessors and the original of their mother tongue. In 1715 she published: *The Rudiments of Grammar for the English-Saxon Tongue, first given in English: with an Apology for the study of Northern Antiquities. Being very useful towards the understanding our ancient English Poets and other writers*. In her Preface is a long criticism on the value of the Anglo-Saxon element in modern English. Miss Elstob began a work to be called the *Saxon Homiliarium*, a collection of the English Homilies of Ælfric, Archbishop of Canterbury, but this was left unfinished. After the death of her brother William in 1715, Miss Elstob had a great struggle for a livelihood, and returned to Evesham, "to get her bread by teaching children to read and work." Her books and manuscripts, entrusted to a friend for preservation, were lost. Her weekly fee charged to pupils is said to have been at first only a groat. She was befriended first by Bishop Smardridge, afterward by George Ballard and by Mrs. Chappone (the writer on girls' education), who started a subscription for Miss Elstob, which resulted in the purchase of an annuity of twenty guineas. She was then granted help by Queen Caroline till her death in 1737, and eventually Miss Elstob became governess in the family of a peer. Miss Elstob's brother, William (1673-1715), published at Oxford an edition of Roger Ascham's *Letters*, to which he added the letters of Sturmius, Hieron, Osonius, and others to Ascham, 1703. F. W.

*Dictionary of National Biography*; and Miss Elstob's works.

**ELWELL, BENJAMIN STODDERT** (1810-1894).—College president; graduated at the United States Military Academy in 1832, and was instructor there for four years. He was professor of mathematics at Hampden-Sidney College, Washington (Va.) College, and the College of William and Mary. From 1854 to 1881 he was president of the latter institution. W. S. M.

**ELYOT, SIR THOMAS** (1499?–1546). — One of the outstanding educational writers of the Renaissance period in England. Elyot was probably born in Wiltshire. His father was a judge, first of assize, then of the common pleas. Sir Thomas Elyot was not apparently a student of either Oxford or Cambridge University, but was associated, nevertheless, with the group that Sir Thomas More gathered round himself at Chelsea. Early he devoted himself to medical studies, and informs us that before the age of twenty he had read over most of the ancient and medieval authorities. Elyot spent an active life politically, being, like Vives (*q.v.*), connected with the negotiations on the divorce question of Queen Catharine of Aragon. He was sheriff of several counties and M.P. for Cambridge in 1542, and died in 1546. Sir Thomas Elyot belongs to the type of educationist common in his day who had formed his educational views to some extent on a wide practical knowledge of the world, but more essentially on the new Renaissance studies. He was the friend of Colet, Lily, and Ascham, and one of the pioneers of the movement for the study of Greek in England. The *Governour* is a treatise on political philosophy, but it branches out into all the domains of social philosophy, including ethics and education. The view of such a book in an age of absolute monarchy, like the Tudor, was of great importance. That it was written in English gave it still more of popular significance. Besides his indebtedness to Plato and Aristotle, more immediate models were Giovanni Pontano, Philip Beroaldo, and Francesco Patrizi. In spite of all the sources which are suggested for the *Governour*, it marked essentially an epoch in the history of our literature, since it is the first book in the vernacular on moral philosophy. In the *Castell of Helth* Elyot was the first to write on "physic" in English, and tells his critics to remember that if he writes in English, the Greeks wrote in Greek and Romans in Latin, *i.e.* each in their mother tongue. Elyot consistently translated into English such works as portions of Isocrates, St. Cyprian, and Plutarch.

The *Governour* attempts to point out the right education and training of the ruler of the State. But the training which is best for statesmen, he evidently wishes to suggest, is best for any other who can contrive to get it. He sees the importance of the choice of a nurse for the earliest years. Then the nobleman himself is the only adequate instructor of the son. Emulation should be encouraged. Latin-speaking should be begun early and constantly used, by speaking it in the home. If a tutor is appointed, it will be his first duty to know the nature of his pupil. Elyot teaches the Platonic view of music in education, and is most insistent on the importance of drawing and sculpture to train the eye and hand, and be of helpfulness to other studies. It is interesting to note, within fifty

years of Columbus' great discovery, that Elyot realizes that educational subjects should include geometry, astronomy, and cosmography. He objects to the long-continued, tedious use of grammars in teaching Latin and Greek. Even by 1531 Elyot describes Greek grammars as "almost innumerable." Authors to be read by the child by twelve years of age include Æsop's *Fables*, some Lucian, some Aristophanes, Homer, Vergil, Ovid, Silius, Lucanus, Hesiod, Strabo. Then he should study logic, rhetoric, and cosmography. Then history, moral philosophy. Above all, Plato and Cicero should be studied. Elyot is the first English writer to emphasize the importance of physical education. He illustrates the subject with great stores of examples from ancient history. Horse-riding and shooting, *i.e.* archery, he puts in the first place. The first book of the *Governour* deals with education of the nobles; the remaining two books with the moral qualities to be required in the statesman. The whole book is permeated with the Renaissance spirit, abounding in the appeal to antiquity for historical examples of all points urged.

Besides writing the *Governour*, Elyot rendered the service to the practical side of education of compiling the large Latin-English dictionary published in 1538. This was reëdited by Thomas Cooper, Bishop of Lincoln, about 1550, under the title *Bibliotheca Eliotæ*, and finally was issued as *Thesaurus Lingue Romanæ et Britannicæ* in 1565. F. W.

**ELZEVIRS.** — A famous family of book printers and publishers who flourished throughout the greater part of the seventeenth century. The founder was Louis Elzevir, a bookbinder, who came from Louvain to Leyden in 1580 owing to religious persecutions. He pursued his calling, and later began to sell books, finding a clientèle among the students and instructors of the university. He met with little success, however, until he was appointed university bookseller and publisher to the university. Louis opened up a correspondence with the whole of Europe, and contributed not only to his own success, but to the reputation of the university. His first publication was an edition of *Eutropius* in 1592. In 1595 he adopted the trademark of an eagle grasping seven darts in

its claw. The firm began to send representatives to the book fair at Frankfort, to Paris, and all important book centers of Europe. Louis died in 1617, and was succeeded in the business by two of his sons, Matthew and Bonaventure. Many books from their office at this time dealt with the all-important theological questions of the day. The Leyden office entered upon its most flourishing period about 1625 in the hands of Bonaventure and Abraham, a grandson of Louis. In 1625 the office of Erpenius, printer and university instructor, who possessed the only Oriental font in Europe, was purchased by the Elzevirs. In 1629 began the publication in 16mo of Horace and Ovid. In 1641 a series of French drama was issued. By 1652 John and Daniel succeeded their fathers, Bonaventure and Abraham, and published the *Imitation of Christ* and the *Psalms* in that year. In 1655 Daniel moved to Amsterdam. The Leyden office continued successfully until 1681, when it began to decline.

But the better known work was being carried on at Amsterdam, where Louis, a grandson of the founder of the business, opened a bookshop in 1638, and added a printing office in 1640. With the aid of Daniel, who joined Louis in 1655, the house gained great prestige for the important series of publications which it issued, although it is claimed that the Leyden works were typographically better. They popularized literature by introducing convenient editions of the classics in 12mo and 16mo at reasonable prices; they published numerous theological works in Dutch, and brought the works of contemporary foreign writers within reach of the whole of Europe. They had members of the family as agents and representatives in all important literary centers of Europe, and were in touch with the chief scholars and authors of the day. David Heinsius was for long their literary adviser; Salmasius published with them; authors considered it a great honor to be handled by their firm, so that Jean de Balzac sent a letter of thanks to them when they published a pirated copy of some of his works. Many anonymous works which at the time created sensations came from the office of the Elzevirs under a false title page, thus Pascal's *Lettres Provinciales*, and Milton's *Defensio Populi Anglicani*. Few works of importance in classical or contemporary literature failed to find a place in the publications of the Elzevirs, whose reputation among early publishers is only rivaled by Aldus.

**EMBLEMS.** — This term is derived from the Greek *ἐμβλημα* (from the verb *ἐμβάλλειν*) i.e. something thrown in as an ornament. In the usual acceptance of the sixteenth and seventeenth century, an emblem was "a picture and

short posic, expressing some particular conceit" (Cotgrave), or, as Francis Quarles puts it, an emblem "is but a silent parable." These definitions are quoted by the late Rev. Henry Green in his classical account of emblem books *Shakespeare and the Emblem Writers* (London, 1870). In this book, the author distinguishes between the following kinds of emblems: Historical Emblems, Heraldic Emblems, Emblems for Mythological Characters; Emblems illustrative of Fables, Emblems in connection with Proverbs; Emblems from Facts in Nature and from the Properties of Animals; Emblems for Poetic Ideas; Moral and Æsthetic Emblems. Emblems are mentioned in Greek writings, and for their origin probably go back to prehistoric times. The part they played in the course of Christian history can be traced in any history of Christian art, for symbol and emblems run through architecture, sculpture, and painting, as well as literature. Mr. Green further points out that we trace them in "pagan tombs and Christian catacombs of ancient Rome," and through the Middle Ages in the illuminated manuscripts. Astrological compilations and the epoch-making *Speculum Humanæ Salvationis* (c. 1430), the *Biblia Pauperum*, and other block books, especially books of fables, contain emblematic illustrations. The *Narrenschiff* (*Ship of Fools*) of Sebastian Brandt, 1494, brings in the emblem as an acknowledged type of book. By 1522 Andreas Alciat (*q.v.*) published his *Emblematum Libellus* at Milan. Mr. Henry Green has enumerated 176 editions of Alciat's *Emblems*, and of these 163 were issued between 1522 and 1650. One of the books classed as an emblem book was the *Imagini dei Dei degli Antichi*, i.e. "Images of the Gods of the Ancients," published by Vincenzo Cartari (Char-tarius) at Venice in 1556. This served as a dictionary of antiquities, and in its Latin form was used widely in schools, being recommended, for instance, by Charles Hoole, in his *New Discovery*, 1660. Hoole also advises the use of Alciat's *Emblems* as a source for phrases and proverbs required for use in thematic writing. The most extensive list of emblem writers recommended for the schoolboy to consult is that given by Thomas Farnaby (*q.v.*) in his *Index Rhetoricus*, 1625. Farnaby names the following: Alciatus, Rhumelius, Sambucus, Fayrus, Joach. Camerarius, Taurellius, Paulus Maccius, Hadrianus Junius, Catsius, *Elcgidia Epitictica*, Oræus, Taubillius, Theod. Beza. Sambucus was a Hungarian physician, whose *Emblemata* were published in 1564 at the Plantin Press at Antwerp. Beza's *Emblemata* were issued at Geneva about 1581. Catsius was the greatest of the Dutch emblem writers. Farnaby omits from his list the famous Brandus, Boechius, and Jovius. The inclusion, however, in his list of Paulus Maccius, the Italian emblem writer, who published his *Emblemata* at Bologna in 1628, has its interest, since it illustrates a possible method of learning Ital-

ian by having the picture, Latin verses, and Italian verses side by side.

The most important collection of emblems in English in the sixteenth century was that of Geoffrey Whitney in 1586, entitled *A Choice of Emblems*. This was printed and engraved in the house of Christopher Plantin at Leyden. The collection was made from the works of earlier writers, with particular recourse to the authors whose emblem books had been published by Christopher Plantin, though Whitney's selection was not confined to these. It was beautifully reproduced under the editorship of Henry Green in London in 1856. Whitney dedicates one emblem to the Youth at the School of Andlem in Cheshire. This is entitled *Studiis inuigilandum* ("We must be watchful at studies"). The last four lines run: —

For, what I woulde unto myselfe shoulde chauce,  
To you I wishe, wheare I my prime did spende.  
Wherefore behoulde this candle, booke and glasse  
To use your time, and knowe how time dothe passe.

Whitney thus connects his emblems with schools and schoolmasters. One set of verses beneath the emblem describes the schoolmaster of Faleria. Books of emblems clearly appealed specially to the studious, and the schoolmasters such as Thomas Farnaby (*q.v.*) and Charles Hoole (*q.v.*) required boys to consult them. In the work for the fifth form, Hoole (*New Discovery*, etc.) points out that for theme writing and verses, boys should have a large commonplace book into which they collect those picture heads, "emblems and symbols" out of Alciat, Beza, Quarles, Reusner, and Chartarius." Reusner's *Symbola Heroica* had been recommended by John Brinsley (*q.v.*) in the *Ludus Literarius* (1612) as a rich storehouse for materials in theme writing. The book dealt with 154 emperors, giving short characterizations, and treated symbolically. The emperors extend over classical and medieval times, thus introducing the schoolboy to more than ancient history; the mottoes attached to each emperor are moral, and often epigrammatic. Thus there is ample scope for phrase culling. Amongst the English emblem writers Andrew Willet (c. 1598), published a *Century of Sacred Emblems*. Mr. Green quotes the English form of the sixty-seventh emblem, in Latin, on *Puerorum Educatio*: —

A scholler must in youth be taught,  
And three things keepe in minde full sure,  
God's worship that it first be sought,  
And manners then with knowledge pure;  
In church, in scoole, at table must he,  
Deout, attent and handsome be.

Francis Quarles' *Emblems, Divine and Moral*, "the most popular" of all English emblems, were published in 1635. Hoole not only required boys to hunt through Quarles for phrases in theme-writing; he also suggests in the directions for teaching reading in the *Petty School* (1660) that the child should be encouraged to

read "delightful books, of English history, as the *History of Queen Elizabeth*, or poetry, as (George) Herbert's *Poems*, Quarles' *Emblems*," etc. Emblem books were used as reading books. Thus J. Harris published, in 1806, the tenth edition of a book originally published by F. Newbery, entitled: *Choice Emblems, Natural, Historical, Fabulous, Moral and Divine, for the improvement and pastime of Youth. Displaying the Beauties and Morals of the Ancient Fabulists: the whole calculated to convey the Golden lessons of instruction under a new and more delightful dress for the use of Schools.* F. W.

**EMERSON, CHARLES WESLEY** (1837–1909). — Founder of a college of oratory; educated in the common schools and at Boston University. He was instructor of elocution at Philadelphia, and president of the Emerson College of Oratory at Boston (1880–1902). Author of works on oratory and physical culture. W. S. M.

**EMERSON, GEORGE BARRELL** (1797–1881). — Educator and author; born at Kennebunk, Me., 1797, and educated in the district schools, Dummer Academy, and Harvard College, graduating in 1817. He was, two years each, principal of a school at Lancaster, Mass., tutor in Harvard College, and headmaster of the English High School in Boston. He was, however, chiefly interested in the education of girls; and for thirty-two years he conducted a secondary school for young women in Boston. For several years he served as a member of the State Board of Education of Massachusetts. He was one of the founders of the American Institute of Instruction, and was a leading contributor to the *Massachusetts Teacher* and other educational journals. He was joint author with Alonzo Potter of the *School and Schoolmaster*, a popular teachers' manual, and he published *Female Education* and *Reminiscences of an old teacher* (1878), which

originally appeared in Barnard's *American Journal of Education*.

**EMERSON, RALPH WALDO** (1803-1882).—The philosopher, poet, and essayist was on his paternal side descended from six generations of Puritan clergymen. His earliest education was received from his father, the Rev. William Emerson, minister of the First Church of Boston. Attempting to put his sons through a forcing process, he records that at the age of three Ralph did not read very well. Further training was gained through Emerson's aunt, who said the Emerson boys were born to be educated, and who, in turn, was described as a spur, or, better, a ferment in their young lives. This remarkable impetus resulted in Emerson, between the ages of eleven and fourteen, reading French, corresponding with his brother in Latin, and writing a variety of verse in the Georgian style. After some years at the grammar and Latin schools of Boston, with the additional knowledge of a little fiction, some history, and much poetry and rhetoric, Emerson entered Harvard College in 1817. There he describes himself as the youth who had no faculty for mathematics and wept over the impossible analytical geometry, and consoled his defeats with Chaucer and Montaigne, with Plutarch and Plato at night. But what the undergraduate neglected in prescribed studies he made up by omnivorous reading and constant writing of poems, essays, meditations, and journals. In the latter Emerson's independent views on education were promptly set down. He does not think it necessary to understand mathematics and Greek thoroughly to be a good, useful, or even a great man, but he does insist that the student, in his arrangements for residence, should have a chamber to himself and sit alone, and should pay so much honor to the visits of truth to his mind as to record them in a journal. After eking out his living by district school teaching, and after winning several college prizes, Emerson graduated in 1821, taught for a year in his brother's finishing school for girls, began a course in divinity, interrupted by a winter in the South in the search for health, and was ordained in 1829 as pastor of the Second Church, Boston. Resigning in 1832 on account of his indifference to certain sacra-

ments, in 1833 he traveled in Europe, meeting among others Landor, Coleridge, Wordsworth, and Carlyle. On his return home and settling in Concord, there appeared between 1836 and 1838 three notable publications,—*Nature*, *The American Scholar*, and the *Divinity School Address*, which embodied the author's essential views on metaphysics, culture, and theology. In the first appear the fundamentals of his philosophy: self-reliance, or the cultivation of the individual; benevolence, or an optimistic outlook upon mankind; immanence, or the view which holds nature to be the present exponent of the divine mind. The latter appeared close to a dangerous pantheism, and gave such offense to the more conservative that, when carried out in the *Divinity School Address*, the lecturer was shut out of the gates of Harvard for full thirty years.

It was the principle of self-reliance that offered the clew to Emerson's educational theories. Recalling the cast-iron curriculum of his youth, he now protested that colleges can only highly serve us when they aim not to drill, but to create; when they gather from afar every ray of various genius to their hospitable halls (*Works*, Vol. I, p. 93). Appealing to Pestalozzi for his doctrines of liberality and self-help, Emerson further elaborated his conclusions in his address of 1844 on *New England Reformers*. Here he complains that an education to things is not given. We are students of words; we are shut up in schools, and colleges, and recitation rooms, for ten or fifteen years, and come out at last with a bag of wind, a memory of words, and do not know a thing. We cannot use our hands, or our legs, or our eyes, or our arms (Vol. III, p. 257). These strictures of the Concord philosopher were kindred to those of his cousin, George Barrell Emerson, whose memorial to the American Institute of Instruction led the Massachusetts Legislature to appoint as secretary of the new Board of Education Horace Mann, who specifically acknowledged his indebtedness to the Concord sage. The latter's educational suggestions, however, were not directed merely to object teaching and field work, for he confesses in his *English Traits* that the effect of the drill at Oxford and Cambridge was the radical knowledge of Greek and Latin and of mathematics, and the solidity and taste of English criticism (Vol. V, p. 206). Looking over the Oxford examination papers of the year 1848, he believed they would be too severe tests for the candidates for a bachelor's degree in Yale and Harvard. But while he grants that the English students not only read but write better than the American, nevertheless he fears that their universities, because of their insistence on drill and routine, are hostile to genius, for genius is rare, precarious, eccentric, and darkling (Vol. V, p. 213). For this high aim, as the essay on *Culture* insists, should true education seek. The hardest skeptic who has seen a horse

broken, a pointer trained, or visited the exhibition of the industrious fleas, will not deny the validity of education, — but what an education! Our people prefer the schoolmaster who likes strict rules. They send the child to the Latin class, but they ignore the fact that much of his tuition comes on his way to school, from the shop windows. They seldom realize that individuality is not only not inconsistent with culture, but the very basis of it (Vol. VI, p. 142).

Having been a teacher for four years in city and country schools, a lecturer in local lyceums in all parts of the country, a member of the school committee of Concord, and one of the Board of Overseers of Harvard College, Emerson concluded that scholarship should be created, not by compulsion, but by awakening a pure interest in knowledge. His perfect aim was summed up in a final essay on *Education*, the principles of which are the author's lifelong appeal to individuality and idealism. Seeing, with Leibnitz, how much education may be reformed, he urged that its scope should be as broad as man, and that its object should be a moral one — to teach self-trust. The secret of education lies in respecting the pupil; its two capital facts consist of genius and drill. The one of these is obtained by the will, the male power, which organizes and impresses its own thought and wish on others; the other is fostered by sympathy, the female force, more subtle, lasting, and creative. It is by wit, fancy, and imagination that we can nourish the inspiration in the well-born healthy child.

**ÉMILE.** — The title of an epoch-making work in the history of education, by Jean Jacques Rousseau (*q.v.*). The full title is *Émile ou de l'Éducation*. It inaugurated the period of the New Education, more fully developed by Pestalozzi and Froebel. It was a protest against an education which aimed purely at conventional information, and was a plea, in perhaps exaggerated form, for natural and healthy development of the child. The keynote to the whole work is sounded in the first sentence: "Everything is good as it comes from the hands of the Author of nature; but everything degenerates in the hands of man."

See ROUSSEAU, JEAN JACQUES.

**EMMETROPIA.** — See EYE, HYGIENE OF.

**EMORY AND HENRY COLLEGE**

**EMORY, VA.** — Founded by the Holston Conference of the Methodist Episcopal Church, South, in 1835, and opened to students in 1838. The original intention of making the institution a manual labor school met with little success, and was soon dropped. The campus contains twenty-three acres, on which are located the dormitories and recitation halls. The entrance requirements are equivalent to about fourteen units. Courses are offered leading to the degrees of Bachelor of Arts and Bachelor of Science. In 1909 there were enrolled in the college 109 students. The teaching staff numbers twelve.

**EMORY COLLEGE, OXFORD, GA.** — An institution established by the Georgia Conference in 1836. Sub-freshman, college, and postgraduate courses are offered. Admission is by examination, or by certificate from an approved high school. The degrees which are conferred after a regular college course of four years are Bachelor of Arts, Bachelor of Philosophy, and Bachelor of Science. In 1909 there was an enrollment of 294 students. There is a faculty of fifteen members.

**EMOTION.** — A term used by careful writers to refer to a complex feeling process. Thus anger is an emotion; it is made up of disquieting feelings, which are in part organic, in part of a higher order depending on a sense of injustice, which in turn arises through a comparison of the present situation with standards set up through past experience. One is angry, for example, when he sees a driver beating a horse, partly because any suffering animal arouses certain sympathetic bodily responses, and partly because he has standards of treatment of animals which are outraged by the present scene.

Emotion is to be contrasted with thought or knowledge processes. Thus, when one is angry, he is not a careful observer of all the perceptual details of the situation before him. One cannot sit down and read a book when he is experiencing a violent emotion. For reasons like these, the classifications adopted in all psychologies have distinguished sharply between knowledge and emotion. The distinction between emotion and volition is much less clearly marked. To be sure, a paroxysm of anger may incapacitate one so that he is unable to do anything. This is, however, an extreme case. The more common fact is that one is impelled to action just in the degree to which he is emotionally aroused. The angry man may not go about the attack upon his enemy with clear insight and wisdom, but he is very likely to exhibit great energy and persistence.

The relation between emotion and action has been brought into great prominence in the last two decades by the discussions of Lange

and James (James-Lange theory). These two authors drew attention to the fact that a violent bodily reaction in many cases precedes the emotional consciousness, and conditions it. Thus, the melancholic patient has certain characteristic visceral contractions. These are in no wise due to conscious states. They may be due to purely physical causes to be sought in the organism and its state of nutrition. These visceral contractious condition, however, a state of consciousness so powerful and enduring that sooner or later the mental life of the patient will be completely centered about the depressed emotional state. In like terms James points out that the true order of processes is not impression, emotion, action; but in many cases the impression issues immediately in action, and the emotion follows after the action is well under way. Thus one sees danger approaching. He starts to run, or his muscles grow rigid in instantaneous contraction. After the act is well advanced, there arises in experience the emotion of fear. Likewise, in James' terms, we are sorry because we weep; it is not true that we weep because we are sorry.

The theory of the emotions above set forth lays great emphasis upon the external bodily act. This emphasis is extreme. When James says, for example, that there is nothing in an emotion if the muscular activities are inhibited, he fails to do justice to the nervous processes which are the real central causes of both the emotion and the activities. Feeling and emotions depend directly upon nervous conditions. These nervous conditions are undoubtedly motor rather than sensory in type, as may be seen by the analysis of any emotional situation. Thus, the same person may, on two successive occasions, have two totally different emotions in the presence of exactly the same sensory stimuli. When one is reading, a noise disturbs him. When he is ready to go out for a walk, and waiting for the summons of his companion, the same sound may give him great pleasure. The sound cannot explain the displeasure or the pleasure, when it is treated merely as a sensory impression. The sound arouses, in the two cases described, two totally different types of responses. In the reader, the motor processes run counter to the whole set of activities now established. There is confusion in the inner nervous centers. There may be slight muscular response, but the nervous commotion may be great. In the listener, the sound releases a pent-up artillery of motor processes. The exhilaration of released expectation gives satisfaction. Such an analysis as this gives full weight to the motor relations of the emotions, without identifying them with muscular processes.

The foregoing analysis of emotional processes introduces an important line of consideration, which is suggested by James, and more fully carried out by MacDougall (*Social*

*Psychology*). The emotions are very largely conditioned by instinctive organizations. Thus, when an animal is organized to perform a certain type of activity, it derives great satisfaction from that type of activity. A kitten is organized so as to stalk prey and seize it by a sudden leap. This instinctive tract is so fully organized in its nervous system that from earliest days on the kitten derives pleasure from the pursuit of real or imaginary prey. The rolling ball sets the kitten's organized motor processes in operation. The action is instinctive and natural; the emotion follows naturally upon the motor discharge.

Pleasure attaches not merely to instinctive behavior; a well-organized habit is also a natural and agreeable mode of behavior. This comes out most clearly through the negative example. A man who has always been in the habit of going about the routine of his office in a given way will be irritated beyond degree by trivial irregularities. There is nothing so exasperating as to be interrupted in the routine of dressing by the loss of a necessary part of one's apparel. Such examples make it clear that we are continually organizing our emotional tendencies through the habits which we acquire, and the instincts which we allow to develop.

One conspicuous example of cultivated emotional possibilities will be found when one studies any of the arts. Music began in the primitive beating of dull noise-producing objects in rhythmical succession. The rhythm was a natural expression of a fundamental mode of nervous behavior. Because the nervous tissue naturally acts in rhythms, and because the sound in its successive actions upon the nervous tissue coincided with the natural tendency and reinforced it, the primitive musician enjoyed the rhythmical noise. Soon there came to be a selection of sounds that had pitch. The rise and fall of pitch, the accentuation and sympathetic accompaniment of the noise by vocal chord reactions, increased the satisfaction. Now came a growth in the range and modulation of sounds. Then followed combinations of melodies; finally, the growth of harmony. Any genetic study of the arts makes it evident that man grew in emotional appreciation through the cultivation of activities appropriate to the art.

The foregoing analysis introduces the much-discussed problem of education of the emotions. It is often asserted that the school is purely intellectualistic, that the emotional side of the child's nature is neglected, that we do not find in the school the well-rounded nature which should be cultivated in the normal child. Various suggestions have been made as to methods of correcting this supposed defect. Some of these suggestions appear under the doctrine of interest (*q.v.*). Herbart and Spencer both point out that natural mental development always leads to forms of mental activity

which are pleasurable. The important corollary to this statement is that anything can be made pleasant through cultivated habit—except the more violent forms of experience which work organic harm. If we can believe the stories told of devotees who perform weird rites of self-destruction, there may be pleasure even in these injurious forms of activity. When, therefore, the question of pleasure in education is seriously discussed, it should be with such broad consideration of the nature of emotion clearly in mind.

Is it ever legitimate to define educational aims in terms of emotions? The foregoing psychological analysis would seem to lead to a negative answer to this question. Emotion is a significant symptom of the way in which an impression arouses an organized being. Emotion may serve to show the individual himself how he is tending in his habits. But emotion can never be discussed intelligently apart from the discussion of habits of reaction. When one is pleased with a piece of news, it shows that the news comports with his plans and tendencies toward action; but the pleasure is never an end in itself. If one would learn to enjoy an art, he must train himself in appreciation and sympathetic modes of response.

If the school will train in right modes of behavior, the emotional symptoms will properly adjust themselves. The teacher should watch the emotions, for they are valuable means of diagnosis. When a child is sulky and displeased, there is an incoordination somewhere. It does not follow that the situation should be modified in the direction of the child's present tastes. The best possible education for the child may be one of retraining his habits, so that he shall have an entirely different attitude. Nor is it true that anything which gives the child pleasure is therefore bad. If the child is normal, and his environment wholesome, there will be a preponderance of pleasurable experiences in his life. The school should find in this principle guidance and motive for organization of that which is natural. The school should never be misled into the fallacy of regarding emotion as a primary end of training.

**EMOTIONAL EXPRESSION.**—In a volume entitled *Expression of the Emotions in Men and Animals*, Charles Darwin called attention to the necessity of offering some scientific explanation of the complex behaviors which accompany emotions. Darwin regarded these emotional expressions as rudimentary forms of earlier activities which were of im-

portance in the practical life of the animal expressing the emotion. Thus, the frowning of an angry animal is, according to Darwin, the rudimentary form of a facial expression which was natural and useful in combat. The attention which Darwin's book drew to the emotions is undoubtedly responsible for the later discussions, such as those of James in his theory of the emotions (*q.v.*). There are suggestions also in Darwin's work of the relation between emotions and instincts as emphasized in MacDougall's *Social Psychology*. The emotional reactions of human beings have of late been made subjects of elaborate studies in psychological laboratories. The circulation of the blood has been studied with reference to its modifications during emotional states. Other internal activities, such as those of the digestive organs, have also been studied. Cannon was able to show that a cat excited emotionally during the process of digestion is seriously interrupted in the normal process of peristaltic action. A change in the tension of the voluntary muscles also takes place during emotion. This has been repeatedly shown in experiments with the ergograph (*q.v.*) and dynamometer. There is an intimate relation between emotional expression and attention.

**EMPIRICAL PSYCHOLOGY.**—See PSYCHOLOGY, EMPIRICAL.

**EMPIRICISM.**—A term currently defined as the doctrine that all knowledge is derived from experience and is to be tested in the last analysis by an appeal to observed facts and not by an appeal to theories about these facts or to principles of thought which are supposed to underlie all observation. Locke's *Essay concerning Human Understanding* (1690) is still the classical exposition of this doctrine, and there is, perhaps, no more precise statement of it than is found in his words: "Let us then suppose the mind to be, as we say, white paper, void of all characters, without any ideas; how comes it to be furnished? Whence comes it by that

vast store which the busy and boundless fancy of man has painted on it with an almost endless variety? Whence has it all the materials of reason and knowledge? To this I answer in one word, from experience; in that all our knowledge is founded, and from that it ultimately derives itself. Our observation employed either about external sensible objects, or about the internal operations of our minds, perceived and reflected on by ourselves, is that which supplies our understandings with all the materials of thinking. These two are the fountains of knowledge from whence all the ideas we have or can naturally have do spring" (Bk. II, ch. i, sec. 2). Empiricism, thus conceived, was primarily a protest against the contention that there are innate ideas and intuitive principles which afford a source of knowledge of greater authority than observation itself. In other words, Locke held that thinking is solely an instrument for discovering what relations exist between observed facts and what may be expected from them, and that it is controlled not by principles of its own, but by the character of the material with which it deals. Locke's doctrine found its immediate antithesis in the philosophy of the Cartesians, who maintained that, given definitions and propositions of intuitive certainty, knowledge of scientific validity could be deduced from them without the confirmation of observation; and its later antithesis in the philosophy of Kant and his successors, who maintained that experience involves more than observation, namely, the working over of the material of observation according to principles of combination which that material itself does not yield. The Cartesian view has been known historically as rationalism, and the Kantian as critical empiricism or criticism. Some of Locke's followers, notably Condillae (*q.v.*) (1715-1780), carried his doctrine to the extreme of affirming that experience is a matter of sense impressions exclusively. In this form empiricism is known as sensationalism.

If the doctrine of empiricism is considered in an historical setting wider than that determined by interest in the philosophy of Locke, it will be found to rest on the antithesis, as old as reflective thinking, between theory and practice. The term "empiricism" is derived from the Greek *ἐμπειρία*, which, in the time of Plato and Aristotle, appears to have become the generally recognized name for bodies of knowledge consisting of a collection of observations, as distinguished from those consisting of a system of coherent principles. Thus Aristotle says: "In view of practice experience is in no respect inferior to science; on the contrary we observe that those who have experience are more successful than those who have theory without experience. The reason is that experience is knowledge of individual cases, while science is knowledge of universals, and practice and genesis have in every case

reference to the individual. For the physician does not cure man, except incidentally, but he cures Callias or Socrates or some one of those similarly named, who happens to be a man" (*Metaphysica*, 981a 13ff.). The greater serviceableness of empirical knowledge thus recognized by Aristotle has been repeatedly emphasized in the history of thought. The Stoics and Epicureans—notably in the conception of the mind as a *tabula rasa* by the former—tended to construe knowledge wholly as a collection of individual observations, and thus to approach the theory of Locke. In the Middle Ages the perfection given to deductive systems and the consistent arrangement of definitions and propositions produced a reaction in the interest of more empirical methods. The nominalists generally were influential in the reaction, but the greatest contribution of the Middle Ages to the development of empiricism was made by Roger Bacon (*q.v.*). The sixth part of his *Opus Majus*, entitled *De scientia experimentalī*, is remarkable for its illustrations of empirical methods. "Because we know nothing adequately without experience," he urged radical reforms for the advancement of science and the betterment of education based upon empirical principles. During the Renaissance, particularly with such men as Leonardo da Vinci (1452-1519), Vives (1492-1546), Campanella (1568-1639), and Galileo (1564-1642), the claims of empiricism grew. In these men interest in the methodology of empiricism is discoverable. It was not, however, until the publication, in 1620, by Francis Bacon, of his *Novum Organon*, that this methodology received anything approaching a comprehensive formulation. Affirming that the understanding left to itself (*intellectus sibi permissus*) can accomplish nothing, he insisted that knowledge advances profitably only when checked and controlled by systematic experimentation and the collection of observations according to rules. To these rules he gave the first generally recognized formulation. Considerable advance in this direction was made by Sir John Herschel by the publication in 1830 of his work *On the Study of Natural Science*, which was one of the chief sources of the *System of Logic* published by John Stuart Mill (*q.v.*) in 1843. Mill's remarkable book undertook to set forth a complete logic and methodology of empirical research, and, although modified in details by subsequent writers, has not yet, as a whole, been superseded.

Locke's doctrine, which received some extension in the writings of Berkeley (*q.v.*) (1685-1753) and Hume (*q.v.*) (1711-1776) and the British associationists, is perhaps the most characteristic product of British philosophy. On the Continent, the Kantian influence has led not only to the idealistic systems of thought with which its development is usually associated, but also to new forms of empiricism, usually known as "pure empiricism." Of

this the *Kritik der reinen Erfahrung* (1849) of Avenarius, the *Analyse der Empfindungen* (1885) of Mach, and the *Einleitung in die Philosophie* (1905) of Cornelius are typical. In these writers the attempt is made to free the concept of experience from the psychological entanglements in which it is involved when experience is construed as the method by which the mind is supplied with the materials of knowledge. By "pure experience" they mean the irreducible data or material out of which such distinctions as those of the individual and his environment, the physical and the psychical, thought and things, are generated. Recent important contributions to empiricism have been made by James in his articles entitled *A World of Pure Experience* (*The Journal of Philosophy, Psychology, and Scientific Methods* for 1904) and his *Pragmatism* (1907); and by Dewey in his *Studies in Logical Theory* (1903) and *Influence of Darwin on Philosophy and other Essays* (1910). What is, perhaps, most characteristic of these writers is the recognition, particularly in Dewey's "radical empiricism," of various sorts of experience, such as aesthetic, cognitive, and moral. With Dewey, experience is not the method by which knowledge is acquired, but knowing is a method which experience develops for the organization and control of the situations wherein it becomes uncertain or problematic.

Educational theory and practice have been affected in two principal directions by the doctrine of empiricism. The first of these is illustrated in the program for the reformation of the sciences and the advancement of learning set forth by the two Bacons. While insisting that education should strengthen individual character, they believed that its main ideal is the progress of civilization, the betterment of the economic and physical conditions of life, the progressive conquest of nature by observation and experiment. This spirit in education is peculiarly typical of empiricism. It has always encouraged enlargement of the scope of the curriculum, fostered the development of natural science and industrial education, and promoted the extension of observational and laboratory methods. The second direction in which empiricism has affected education is illustrated in the influence psychology has had on educational practice. The doctrine of empiricism gave to modern psychology its great impetus, for the working out of its theory of knowledge involved no less a task than writing the natural history of the mind. From the consequent advances in psychology have largely come the consideration of genetic methods in education and the efforts to accommodate instruction and studies to the individual's interest and to the stages of his mental growth.

**EMPLOYMENT OF CHILDREN.**—See ATTENDANCE, COMPULSORY; CHILD LABOR.

**EMPORIA, COLLEGE OF, EMPORIA, KAN.**—A coeducational institution founded in 1882 by the Presbyterian Synod of Kansas, with the assistance of a contribution from the citizens of Emporia. The college campus now contains thirty-eight acres of ground. Academic, music, and collegiate departments are maintained. The requirements for admission are equivalent approximately to fifteen units; certificates of accredited schools are accepted. In the college instruction is given in the English Bible as a required part of the course of study for which credit is given. Degrees are granted at the end of four years' study in one of the following groups: classical, English, modern language, scientific, pre-medical, and pre-engineering. There is a faculty of twenty-one members.

**EMULATION.**—The instinct or desire to equal or excel others is a motive much used by teachers. The forms of its utilization vary from the most intense personal rivalries and competitions for grades and prizes to the milder ambitions for excellence as determined by impersonal standards, marks, and promotions. Sometimes the emulative impulses of children are stirred by the granting of additional school privileges and immunities, such as days of vacation, exemptions from examinations, etc. The tendency of modern practice is away from the uses of emulation which are characterized by sharp personal competition and end in unsocial attitudes of pupils toward each other, and in the direction of the measurement of qualities and attainments in terms of one's own previous achievement or in terms of conventionalized standards of efficiency. See REWARDS AND PUNISHMENTS.

**ENCYCLOPEDIA.**—The term "encyclopedia" is from the late Latin, occurring (it is said as a false reading) in manuscripts of Pliny, Quintilian, and Galen, in which it was used as a transliteration of *ἐγκυκλοπαιδεία*, a Greek word erroneously formed from the Greek *ἐγκύκλιος παιδεία*, meaning encyclical, or universal, education; that is, the liberal curriculum, or the circle of arts and sciences considered by the ancient Greeks as essential to a liberal education. (See LIBERAL ARTS, SEVEN.) Hence "encyclopedia" came to be applied to works treating of all the various departments of knowledge, or to works treating of some particular subject in all its aspects or branches. It is, in general, in this sense that the term "encyclopedia" is now applied to many works

extending through the Middle Ages down to about the middle of the seventeenth century, and to various occasional works of a later date. They are in general both in subject matter and arrangement treatises or groups of treatises intended and adapted more for continuous reading or for study than for casual reference. They are also characterized, to a greater or less extent, by having been written by one man or two men, who treated not only the subjects in which they were specialists, but also others of which their knowledge was derived from miscellaneous sources, and not infrequently from hearsay.

Varro (B.C. 116–27) wrote a treatise on the *Libri Novem Disciplinarum*, which dealt with the subjects of the liberal education, medicine and architecture being added to the series, which later became traditional. The earliest extant work of the encyclopedic character is the Natural History of Pliny the Elder (A.D. 23–79), which in the nature of its material bears more resemblance to our modern encyclopedias than many later works. It is a work of thirty-seven books, containing a mass of undigested information on cosmography, astronomy, geography, geology, zoology, anthropology, medicine, metallurgy, mineralogy, and the fine arts, as these subjects were then known. This information was gathered by Pliny in the leisure hours of his public employment; and his work was universally known and of high authority throughout the Middle Ages. Pliny's work was followed, in the earlier centuries of the Middle Ages, by various minor ones, including the *De Nuptiis Philologiae et Mercurii*, forming the first two books of the work sometimes called the *Satyra* or *Satyricon*. This was written, about 470 A.D., by Martianus Minæus Felix Capella (q.v.), an African scholar, self-styled "the foster-child of the city of Elissa." It is largely in verse, and professedly gives an account of the marriage of Mercury to Philology, personified as a learned maiden. The seven liberal arts, personified, give an exposition of their branches of learning, and the work was widely used as a textbook in the Middle Ages. A work of more erudition was the *Etymologiarum Libri XX*, or *Origines*, written early in the seventh century by Isidore (560?–636) (q.v.), Bishop of Seville, which included a treatment of theology, angelology, and Hebrew antiquities. This work is the basis of the *De Universo*, or *De Natura Rerum*, of Rabanus Maurus (q.v.) (776–856), Archbishop of Mainz. About the tenth century there appeared a work compiled by one Suidas, of whom nothing further is known; it was primarily a lexicon, but contained also much encyclopedic matter, including historical and theological material, besides biographical and geographical information, so that in character it is suggestive of the modern encyclopedic dictionary. The encyclopedic part of it is the

source of much of our important knowledge of the writers and languages of antiquity.

The greatest encyclopedia of the Middle Ages is the *Bibliotheca Mundi*, or *Speculum Majus*, compiled by Vincent de Beauvais (q.v.) (d. about 1260), a Dominican friar. This is a work of real scholarship, and constitutes a vast storehouse of the knowledge of that age. In the printed editions it is divided into four parts;—*Speculum Naturale*, treating of natural history; *Speculum Doctrinale*, giving an epitome of scholastic learning; *Speculum Morale* (considered to have been added by some other person), treating of ethics or moral philosophy; and *Speculum Historiale*, giving the history of the world down to 1244.

Other encyclopedias of this early time were *Li Livres dou Tresor*, written in French, by Brunetto Latini (c. 1230–1294), a Florentine poet and grammarian, in exile in France; the *De Proprietatibus Rerum*, by Bartholomæus de Glanvilla (fl. c. 1370), an English Franciscan; and other works of minor importance, or restricted subject matter, such as that of Petrus Berehorius, or Pierre Bercheure (d. 1362), a French Benedictine; that of George Reisch (q.v.), a German prior of the latter half of the fifteenth century; that of Raphael Maffei (1451–1522) of Volaterra, which gives greater importance to geography and biography than any of its predecessors; and that of Paulus Scalichius de Lika, a Hungarian count, entitled *Encyclopædia seu Orbis Disciplinarum*, etc., which was the first work to include the term "encyclopedia" as a part of its title. In 1501 George Valla published in Venice, his *De Expectandis et Fugiendis Rebus*.

In 1630 appeared the *Encyclopædia Septem Tomis Distincta* of Johann Heinrich Alsted (q.v.) (1588–1638), which is the first work to use the term "encyclopedia" in its modern sense, as in itself implying an encyclopedic treatment; and which, also, immediately precedes the transition to the modern system of placing the subject matter under titles alphabetically arranged. The controlling aim in the arrangement of these early works was to present a systematic view of the different branches of knowledge treated, showing their interrelations; and various works of the same general type have appeared in modern times, mainly in Germany in the eighteenth and nineteenth centuries, treating, for the most part, of some particular philosophical system. Among such works are Eschenburg's *Lehrbuch der Wissenschaftskunde* (1792), Schmidt's *Allgemeine Encyclopædie und Methodologie der Wissenschaften* (1810), and Hegel's *Encyclopædie der philosophischen Wissenschaften* (1817).

The change to the alphabetical arrangement marked a corresponding change in the uses to which the encyclopedia was put; it was becoming the book of general reference rather than a work mainly for scholars or students. This purpose of general reference had pre-

viously been served by elaborate and laborious indices; but the modern combination of a dictionary arrangement with encyclopedic subject matter is simpler and less laborious. It involves, however, when fully carried out, as in the typical encyclopedia of to-day, an abandonment of the broad and inclusive treatment of a whole science or a branch of science for the explanation or description of subject matter which is indicated by titles designative merely of phenomena, isolated facts, persons, places, theories, etc. It has also involved a radical change in the manner in which encyclopedias are made. The best modern encyclopedias are not merely careful compilations, but largely works of original composition and authority, written by a large number of men who write as specialists having original and authentic knowledge of the subjects which they discuss. The dictionary arrangement has also led to many encyclopedias being entitled dictionaries or lexicons. There has also been a radical change in the nature of the illustrations; whole-page plates in which were grouped illustrations of things treated at different places have given place to scattered illustrations, each accompanying the text to which it relates. The pictures of objects in nature are now truer to their original, because of the change in the character of the drawings themselves, and from the fact that the early illustrations were largely made from memory, not to say, at times, from hearsay with a large license to the imagination, where the modern pictures are chiefly from photographs.

The earliest important alphabetically arranged encyclopedia was *Le grand dictionnaire historique, ou le mélange curieux de l'histoire sacrée et profane* by Louis Morré (1643-1680), published at Lyons in 1674. This was a notable work, and the best of its kind at the time of its publication. It passed through many editions in which it was variously revised, and was translated into most of the languages of Europe. An important and valuable work by Pierre Bayle (1647-1706), entitled *Dictionnaire historique et critique*, published in 1695-1697, was originally intended to correct the errors and supply the omissions of this and other works, but developed into an independent work. This work passed through many revisions, and was translated into English and German. The French Academy published in 1694 an encyclopedic dictionary named *Le dictionnaire des arts et des sciences*, compiled by Thomas Corneille (1625-1709), which was followed by various other similar works by other authors. Among the Italians Marco Vincenzo Coronelli (1650-1718), a Franciscan friar and geographer, planned a work which was to include articles on all subjects arranged in a strictly alphabetical order. Only seven volumes were published, and these were so inaccurate as to render them of little value.

In Germany, Johann Hübner (1668-1731), a geographer of Hamburg, was the author of the prefaces to two encyclopedic dictionaries which were published at Leipzig under his name, but were the work of various authors, the first dictionary being published in 1704 and the second in 1712. These works were often reprinted during the eighteenth century. In 1721 there was published in Leipzig, by Johann Theodor Jablonski (c. 1654-1731), an encyclopedia including the subjects of theology, history, geography, biology and genealogy, and entitled *Allgemeines Lexicon der Künste und Wissenschaften*, which has been reprinted in various revised editions. One of the most notable of all the encyclopedias or dictionaries of the eighteenth century was that written largely by Johann Heinrich Zedler (1706-1760), a German bookseller at Leipzig. It was entitled *Grosses Vollständiges Universal-Lexicon*, etc., and was published in sixty-four volumes. It was the most comprehensive and exhaustive work of its kind, and was remarkable for including, contrary to the custom of that day, biographies of persons still living.

In England the first alphabetical encyclopedia was that written by John Harris (c. 1667-1719), a London clergyman. It was entitled *Lexicon Technicum, or an universal English Dictionary of Arts and Sciences*, and was published in 1704, at London. In 1728 appeared the first of the great English encyclopedias of to-day. It was published by Ephraim Chambers, and was entitled *Chambers' Encyclopædia, or a Universal Dictionary of Arts and Sciences*, etc. One of the subsequent editions of this work was the basis of the excellent encyclopedia published by Abraham Rees in 1778-1788.

In 1751 there appeared, in Paris, the first volume of the *Encyclopédie ou Dictionnaire raisonné*, etc., which has come to be called *par éminence* the *Encyclopédie*. This great work was originally planned as a translation of *Chambers' Encyclopædia*, but was developed by Diderot (1713-1784), who was the first to undertake the work, into what proved to be the organ of the enlightened thinkers of the period, and exerted an almost revolutionary influence upon the culture of Europe. With Diderot was associated as editor D'Alembert (*q.v.*), until his desertion in 1759; besides his editorial work, he wrote the preface to the work. Among the contributors were included many of those who laid the basis for the social and political revolution of the next generation, including Voltaire, Rousseau, Daubenton, Mallet, Grimm, Quesnay, Turgot, Marmontel, Holbach, Duclot, and Jaucourt. The attitude of the work was socially, politically, and religiously unorthodox, and it provoked violent opposition from the clergy and the conservatives of the old régime, and persecution for Diderot. (See ENCYCLOPÉDISTES.)

In contrast to this encyclopedia, which was also largely a dictionary proper, was the *En-*

*cyclopædia Britannica*, the first edition of which was completed in 1771, being published, at Edinburgh, in numbers or parts. The plan of the work was to treat the arts and sciences as a series of distinct treatises, with numerous references or briefer articles arranged with them in alphabetical order. Who was the originator of the plan is uncertain, some evidence pointing to a printer William Smellie (1740 to 1795), other to one Colin Macfarquhar. The ninth edition of this work (published from 1875 to 1888) includes a series of essays or treatises upon the arts and sciences and of extended articles in history, biography, and theology that are most remarkable for accuracy and scholarship. This edition is suited chiefly for the use of the scholar or specialist; but the subjects treated were made available for reference by an elaborate index published with a supplement in 1902. The eleventh edition, published in 1911 by Cambridge University, England, has been modified in various ways calculated to render the work suitable to meet the needs of a wider public.

The earliest work to present the form of the typical modern encyclopedia, suited for use by the general public as a book of reference, was the German work, *Brockhaus's Konversations-Lexikon*, the first edition of which was published 1796-1808. This work, planned and published by Friedrich Arnold Brockhaus (1772-1823), a German publisher, embodied the idea of using many small articles instead of protracted essays, and gives information upon contemporary matters of biography, politics, etc. A mixture of the encyclopedic and dictionary forms is presented by various modern dictionaries, typically in the *Century Dictionary*, which, besides being a dictionary of English in the ordinary sense, is largely encyclopedic in its titles and subject matter, but excludes biography and geography from its main vocabulary. The French *Dictionnaire universel encyclopédique* of Pierre Larousse combines a brief, but complete, encyclopedia with a general dictionary, as does also, in a briefer scope, the Spanish *Diccionario Enciclopédico de la Lengua Castellana* of Elias Zerolo.

All the preceding works, except as noted, are more or less general in their scope; but from the last part of the nineteenth century there has been a notable growth of special encyclopedias upon a multitude of subjects, some of them of great merit for their learning and a few for their literary qualities.

Among the more important of the special encyclopedias now published are: *Cyclopædia of American Biography*, 6 vols., 1886-1889. *Dictionary of National Biography*, 1st ed., 63 vols., 1885-1900, suppl. 1901; 2d ed., 22 vols., 1908. This is a work of the highest authority, and contains many extended articles of high literary and critical merit. The original editor was Sir Leslie Stephen, who retired on account of ill health, and was succeeded by

Sidney Lee. Besides the work contributed by these two, there were articles by 653 other contributors, the whole work covering upwards of 29,000 biographies of British people, not living. *Cyclopædia of American Horticulture*, L. H. Bailey, ed., 4 vols., 1900-1902. *Encyclopædia of Agriculture* (British), 4 vols., 1907-1909. *Encyclopædia of Accounting*, 8 vols., 1903-1909. *Dictionary of Architecture and Building*, Russell Sturgis, ed., 3 vols., 1901, a work of extended description with biographies, and many artistic illustrations. *Grove's Dictionary of Music*, 2d ed., edited by J. A. Fuller Maitland (original editor Sir George Grove), 5 vols., 1904-1910; a very full and scholarly work containing historical and technical matter as well as many biographies. *Jewish Encyclopedia*, 12 vols., 1901-1905, covering Jewish history, religion, literature, and customs. *Encyclopædia Biblica*, 4 vols., 1899-1903, historical and archaeological in its content, edited and largely written by F. K. Cheyne. *Dictionary of the Bible*, 4 vols., 1898-1902, supplementary volume 1904, historical, archaeological, and exegetical, edited by James Hastings. *New Schaff-Herzog Encyclopædia of Religious Knowledge*, 12 vols., 1908-, edited by Samuel Macaulay Jackson. This work is very inclusive in its scope, and is especially full and accurate in its biographies of medieval and early English divines. In 1908 began the issue under the editorship of J. Hastings of the *Encyclopædia of Religion and Ethics* which is to be completed in ten volumes. The *Catholic Encyclopedia* (1909-) to be completed in fifteen volumes is devoted to "the constitution, doctrine, discipline, and history of the Catholic Church."

Among the more important encyclopedias now published in the languages of modern Europe are:

In English: *Chamber's Encyclopedia* (1888-1892), a British work; *Appleton's Universal Encyclopedia* (1898); *Nelson's Encyclopedia* (1905-1907), smaller than the other works in this list; *Encyclopædia Americana* (1907), notable for its fullness in articles dealing with technical subjects, as mathematics, engineering, and the trades. *The New International Encyclopedia* (1907), which aims to treat all subjects equally with a view to meeting the needs of the average consulter. *Encyclopedia Britannica* (1911).

In foreign languages.—French: *Larousse. Grand dictionnaire universel du XIXième siècle français*, 1866-1890; *Nouveau Larousse, illustré. Dictionnaire universel encyclopédique*, 1898-1904, suppl. 1906. German: *Brockhaus' Konversations-Lexikon; allgemeine Deutsche Real-Encyclopædia*, 14th ed., 1892-1895; *Myers gross's Konversations-Lexikon*, 6th ed., 1905-1909. Norwegian: *Salmonsens's store illustrerede konversationslexikon*, 1893-1907. Swedish: *Nordisk familjebok; konversationslexikon och real-encyklopedi*, 1876-1899. Italian: *Nuova enciclopedia italiana, Dizionario generale di scienze, lettere, industrie, ecc.*, 6th ed., 1875-1888; suppl.

1889-1899. Spanish-American: *Diccionario enciclopédico hispano-americano de literatura, ciencias y artes*, 1887-1899. Russian: *Bol'shaia entsiklopediia*, 1902. Hungarian: *A Pallas nagy lexikona*, 1893.

#### ENCYCLOPEDIAS OF EDUCATION. —

The arrangement and discussion of topics dealing with or bearing on educational theory and practice, either in systematic form or in alphabetical order. The number of encyclopedias which deal specifically with education is small, and is represented chiefly in the German language. Of historical interest is the *Encyklopädische Pädagogisches Lexicon* of I. G. C. Wörle (1835). The earliest work under the modern conception of encyclopedia is that of K. G. Hergang, *Pädagogisches Real-Encyklopädie* (Grimma and Leipzig, 1851, 2d ed.). The first large contribution of more than transitory value was the *Encyklopädie der gesamten Erziehungs- und Unterrichtswesen* (Gotha), edited by K. A. Schmid, the first edition appearing in eleven volumes from 1858 to 1870, and the second in ten volumes from 1876 to 1887. This is a comprehensive work, somewhat too diffuse, dealing with all aspects of education with valuable contributions to the history of education. There is an abridged edition of this work in two volumes under the title *Pädagogisches Handbuch für Schule und Haus* (Leipzig, 1883). In 1865 there was issued *Dictionnaire d'Éducation Publique et Privée*, by D. Raymond as a volume of the *Nouvelle Encyclopédie Théologique*, a Catholic work (Paris, 1865). The first work in English was the *Cyclopædia of Education* edited by H. Kiddle, and A. J. Schem, 1877, followed in 1881 by an abridgement, *Dictionary of Education*, and supplemented annually by the *Yearbook of Education*. The scope of the work is narrow, and deals mainly with American, and, in part, with English educational questions. The statistical portion of the work was for the time the most valuable. The important French encyclopedia of F. Buisson, *Dictionnaire de Pédagogie et d'Instruction Primaire*, appeared in 1882-1888 (Paris), and is now being produced in a second edition. It is in two parts, the first dealing with the history, theory, and organization of education; the second with the subject matter of the primary school and general topics of importance to the teacher. A small work of very limited scope is F. Sander, *Lexicon der Pädagogik* (Leipzig, 1883). A good work in one volume, but without any claim to completeness, is the *Encyklopädisches Handbuch der Erziehungskunde mit besonderer Berücksichtigung des Volksschulwesens* (Wien and Leipzig, 1884) by G. A. Lindner. This work formed the groundwork for the more recent and fuller *Enzyklopädisches Handbuch der Erziehungskunde*, edited by Dr. Joseph Loos (Vienna and Leipzig, 1906), a work in two volumes, giving especial attention to Austrian education and furnishing good bib-

liographies. A second *Cyclopædia of Education* in English was the work edited by A. E. Fletcher and published by Sonnenschein (London, 1892); within the limits of its 562 pages it contains a good deal of useful information. The largest of recent German encyclopedias is the *Encyklopädisches Handbuch der Pädagogik*, edited by W. Rein, a work wholly under Herbartian influences. The first edition appeared in seven volumes from 1895 to 1899; the second, in ten volumes, from 1903 to 1910, is printed in Roman characters. The work, as is to be expected, pays especial attention to German educational problems. It is perhaps not so helpful as might be desired on the biographical and historical sides. Of a more specialized character than any of the works so far mentioned are the *Enzyklopädisches Handbuch der Schulhygiene*, by R. Wehmer (Leipzig, 1904), and the *Enzyklopädisches Handbuch des Turnwesens* by K. Euler (Vienna, 1896).

Different in arrangement are the systematic encyclopedias of education which have appeared in Germany. These works are not arranged in alphabetical order, but are divided and subdivided into main and subsidiary topics. The best and earliest examples of this type of encyclopedia is the *Encyklopädie, Methodologie und Literatur der Pädagogik* (Leipzig, 1861 and 1878), by K. V. Stoy, a work which elaborates the Herbartian principles. The first book deals with the philosophy of education, principles of educational hygiene, theory of education and training, history of education, practice of education, the second book treats of the methodology and literature of education, with directions to teachers for the study of education. To this class belongs the work of A. Vogel, *Systematische Encyklopädie der Pädagogik* (Bernburg, 1881), with numerous references to educational literature within the limits of the topics treated. Rein's *Pädagogik in systematischer Darstellung* (Langensalza, 1906) is a work of the same type as Stoy's, but lacks a good index to complete its thoroughness.

Although falling neither under the class of systematic or alphabetic encyclopedias, Barnard's *American Journal of Education* (1855-1881) must be included here, for, as G. Stanley Hall says, this work is "probably the most valuable periodical ever published in any language, now constituting a vast encyclopedia of information on many, if not on most, topics connected with education" (*Bibliography of Education*, p. 2). A useful index to this work has been published.

Herzog's *Real-encyklopädie für protestantische Theologie und Kirche* (3d ed., Leipzig, 1896-1909) contains valuable educational material of a general as well as religious character. In using this work the index, Vol. 22 (Register) should be consulted under such titles as *Erziehung, Pädagogik; Katechismen und Katechis-*

*musunterricht; Schule und Kirche; Kirchenordnungen; Schulwesen, etc.*

See BIBLIOGRAPHIES OF EDUCATION.

**ENCYCLOPEDIISM.**—The term more specifically applied to that comprehensive conception of education which developed particularly during the seventeenth century, and which emphasized the importance of the universal comprehensiveness of the subject matter of education as opposed to the restrictive humanistic views of the Renaissance education as well as the restrictive views of the scholastic devotees of the traditional seven liberal arts. How the encyclopedic conception of learning was kept alive during the Middle Ages has been indicated in the article on ENCYCLOPEDIA. (See also LIBERAL ARTS, SEVEN.)

Encyclopedism was then kept well before the world by the mediæval educationists in the textbooks produced. Francis Bacon (1561–1626) gave the idea further impetus by prescribing not only an encyclopedic curriculum, but also a method which should inquire into discoverable as well as discovered knowledge, and supply a method of instruction as well as a method of inquiring into scientific knowledge. As Bacon said in writing to Casaubon (*q.v.*), his great desire was "to draw the sciences out of their hiding places into the light." Bacon endeavored in the *Advancement of Learning* and other books to divide the subject matter of the sciences and to give a review of results hitherto obtained. In his *Novum Organum*, he described his method for obtaining new knowledge and filling up the gaps of the old. The greatest encyclopedic schoolmaster of the seventeenth century was, of course, J. A. Comenius (*q.v.*). The title of his *Didactica Magna* shows his encyclopedic purpose (in English translation): *The Great Didactic setting forth the whole art of teaching all things to all men, or a certain Inducement to found such schools in all the Parishes, Towns and Villages of any Christian Kingdom, that the entire Youth of both Sexes, none being excepted, shall quickly, pleasantly and thoroughly become learned in the sciences, etc.* The educational ideal of Bacon was represented in the theory of Ratke (1571–1635), and found more scientific expression in John Valentin Andreae's (*q.v.*) *Reipublicæ Christianopolitiæ Descriptio*. For Andreae required mathematics and natural science to be added to the humanist education. Still more conspicuous were the encyclopedic tendencies of Bacon's teaching reproduced in the *Encyclopaedia Scientiarum Omnium* (1630) of Johann Heinrich Alsted (*q.v.*). This work was the immediate predecessor of Comenius' *Didactica Magna* (1632). Alsted (1588–1638) has been overshadowed by Bacon's reputation, but he was highly spoken of by the great Vossius. Bayle (*Hist. and Crit. Dict.*, Vol. I, p. 234) says Alsted's chief employment was to compose methods and reduce the several

branches of arts and sciences into certain systems. Comenius used the term *Pansophia* for the completed round of ascertained knowledge in the sciences. This would consist in the concise and authoritative statement of all that is known in each science. The summary of Pansophia, therefore, was attempted in the school textbooks, such as his *Janna Lingua Latinae reserata* (1631). John Milton, in his *Tractate of Education* (1644) may rather be considered as a successor of the early Renaissance tradition of educational encyclopedism as found in J. L. Vives' *De Tradendis Disciplinis* than as a successor to the ideas of Bacon (see *Nineteenth Century*, October, 1909, article on a Suggested Source of Milton's *Tractate*). Milton's curriculum included Latin, Greek, Hebrew, Chaldee, Syriac, Biblical history, divinity, church history, politics, law, agriculture, natural philosophy, astronomy, geography, natural history, mathematics, history, engineering, navigation, architecture, medicine, and what we now call biology.

In connection with encyclopedic education the suggestion by the friends of Comenius in England, viz. Samuel Hartlib (*q.v.*) and John Dury (*q.v.*), should be mentioned. These active educationists proposed an *Office of Address*, anticipating the establishment of an office similar to the Bureau of Education in the United States, but more extensive in its aims, which included the cataloguing of all objects of learning, the entering of all new discoveries in learning and knowledge, exchange of hospitality among scholars, correspondence and interchange of introductions to the learned among various countries, a special printing press for the issuing of publications to schools, universities, and learned people. The agents of the *Office* were to act as inspectors "to oversee all schools," and to communicate with all schoolmasters to keep them up to date. To further these encyclopedic objects Hartlib wrote the *Discovery of Public Address* (1648) and his *Further Discovery* (1649), and Dury wrote his *Seasonable Discourse* (1649).

Another source of encyclopedism in education was the necessity of a wider training for the noblemen and gentlemen than was to be found in the ordinary schools and universities. From the courts of Italy in the Renaissance times came the tradition of accomplishments in the arts of living as opposed to *learning*, or at least supplementary to those of learning. In France Louis XIII had established an academy near Jully in 1638, with a curriculum including physical science, mathematics, geography, heraldry, French history, Italian, Spanish. As early as 1599, a German academy had been established at Cassel, the *Collegium Mauritanum*, and in the following century, Germany established on that model a number of Ritterakademien. A number of efforts were made to introduce the academy mainly on the French model into England, but with-

out success. Amongst the attempts were those of Sir Humphrey Gilbert (1572) (*q.v.*); Edmund Boulton (1617) (*q.v.*); Sir Francis Kinaston (1635) (*q.v.*); Sir Balthasar Gerbier (1648) (*q.v.*), Lewis Maidwell (1700) (*q.v.*). Apart from these projects, there was a number of various institutions in London, which collectively were capable of affording encyclopedic education. In 1625 Sir George Buck, in his *Third University of England*, compiled a catalogue or table of all the arts and sciences used and taught "in this University" of London.

As an educational ideal in England, encyclopedism substantially comes to an end with John Locke (1632-1704). In his essay *Of Study* (a posthumous publication) appears the *locus classicus* which gives up encyclopedism. "The extent of knowledge or things knowable is so vast, our duration here so short, and the entrance by which the knowledge of things gets into our understanding so narrow . . . that the whole time of our life . . . is not enough to acquaint us with all those, I will not say which we are capable of knowing, but which it would not only be convenient but also very advantageous to know . . ." With the renunciation of encyclopedism, comes the new anti-encyclopedic conception of education, the *Conduct of the Understanding*. The study of the sciences is to be regarded, Locke there says, "as an increase of the powers and activity of the mind, not as an enlargement of its possessions." The so-called *Enlightenment* (*q.v.*), represented in France by Bayle, Voltaire, D'Alembert, Diderot, Rousseau, and in Germany by Leibnitz and Wolff, was a philosophical school, based on lines of empirical encyclopedism, rather than on metaphysical speculation. Corresponding to each phase of philosophical encyclopedism were various educational theories, until in Madame de Genlis (1746-1830) appeared as advocate for encyclopedic education for both men and women.

**ENCYCLOPEDISTS.** — The name given to the group of scholars, philosophers, theologians, and others who contributed to the *Encyclopédie ou Dictionnaire Raisonné des Sciences, des Arts et des Métiers* (*Encyclopedia or*

*Classified Dictionary of Sciences, Arts and Trades*). This great work was conceived and planned by Diderot (*q.v.*), inspired by the plan of a universal dictionary sketched by Bacon no less than by the success of Chambers' *Cyclopaedia or Universal Dictionary of the Arts and Sciences* (London, 1727). The work was produced under the editorship of Diderot, and, for the early part, D'Alembert (*q.v.*) from 1751 to 1772, amidst the greatest difficulties due to the opposition of reactionary ecclesiastics and government officials. It was produced in twenty-eight volumes, supplemented in 1776-1777 by five more. There was thus provided a rallying point for the representatives of the new school of thought in all branches of intellectual activity, which in its result helped definitely to formulate the prevailing opinions. The most noteworthy of the contributors who threw themselves heart and soul into the work were Montesquieu, Turgot, Rousseau, Buffon, Haller, Condorcet, Quesnay, Grimm, and Voltaire. Fearless criticisms were offered of civil and ecclesiastical authority, at any rate in the volume with which the publisher did not tamper. And the main purpose of the project as it stood out in the minds of the leaders was to spread the light and renew the hope of a better society. "It united the members of rival destructive schools in a great destructive task" (Morley).

The educational opinions which are scattered throughout the work are of interest. They summarize the views of the sense realists, just as on the philosophic side the influence of Locke is seen. Education is defined as the "care taken to nourish, raise and instruct children; its objects are (1) health and good physical development; (2) uprightness and training of the spirit; (3) character, that is, conduct of life and the social qualities." Education is for society, the family, and the State. Each grade of society should be given an education appropriate to it. The aim of education is to secure happiness through the best use of our capacities. Although D'Alembert holds up the public system of Geneva as an example, more attention is given to the education of the children of the better classes, and here the influence of Montaigne is obvious; school education is best only for those who cannot afford a tutor, who is to be carefully selected and make it his business to give his pupil a knowledge of world experiences. The contemporaneous humanistic education is severely criticized, and in its place an education through the senses is advocated. It is difficult to single out any one article as a complete exposition of the educational opinions represented by the work; a full statement can only be attained by consulting numerous articles not on educational topics alone, but in philosophy, politics, and psychology.

**END IN EDUCATION.**—The ends or aims conventionally recognized for education are discipline (the sharpening of the mental faculties so-called), culture, and efficiency. As to both of the latter, either an individual or a social aspect may be emphasized; e.g. efficiency may be measured from the standpoint of power of personal achievement or from the standpoint of capacity to render social service. It is now generally recognized that discipline, efficiency, and culture are set over against one another only when each is taken in a narrow and one-sided way.

From the standpoint of philosophy, the most interesting problem regarding the aim of education is whether it is to be regarded as within or without the educational process; or, to put it in another way, whether education is a means to an end beyond itself or whether education is in some sense its own end. The former conception tends to look around for some external goal to which the educative process is contributory; then education is thought of as a mere getting ready, a preparation for a more or less remote future. From the opposite point of view, some thinkers, notably Emerson, have tended to think of education as itself the end of living, and to conceive wealth, social institutions, art, the external world itself, as having their ulterior value in the educational service they render. The strong point of the conception of culture as the end (when culture has been adequately conceived) is that it recognizes that education is as much an end for the other serious interests of life as they are ends for it. The conception of education as "a continuous making over of experience" is also calculated to avoid the notion of an external and remote end to which education is a mere means. J. D.

**ENDOWED SCHOOLS ACT, ENGLAND**

(1869).—An attempt to organize secondary education in England by regulating the administration of educational endowments through three commissioners, with the assistance of an expert staff. This act, which affected 3000 schools, with a gross income of £592,000, has been the cornerstone of English

policy in regard to secondary education. The act appointed three Endowed Schools Commissioners with power to initiate schemes for the better application of educational endowments. It required that in all schemes provision should be made, so far as was conveniently possible, "for extending to girls the benefits of educational endowments." No endowments less than fifty years old were allowed to be touched by the commissioners without the consent of the governing body, and similar protection was given to schools connected with cathedrals and with the Society of Friends and the Moravians. The endowments of the seven public schools and of public elementary schools were excluded from the control of the Endowed Schools Commissioners. Any scheme framed by the Commissioners was to be sent to the Education Department for approval before being submitted to the Queen in Council. Petitions from persons affected by the scheme were to be considered by five members of the Privy Council, including two members of the Judicial Committee. The Privy Council might direct that a scheme petitioned against should be laid before Parliament. Furthermore, either House of Parliament might present an address against the whole or part of any scheme, in which case it was to be dropped or altered. When finally approved by the Queen in Council, the scheme acquired the force of an Act of Parliament. It made all headmaster-ships of those endowed schools which came under the act tenable by laymen. It protected the religious opinions of pupils in day and boarding schools by elaborate conscience clauses. It gave power to divert to educational uses those endowments, the original purpose of which had become socially obsolete. It enabled the commissioners to remodel the governing bodies of endowed schools upon a more representative basis. But in its original form the bill was far more comprehensive and statesmanlike. It provided for the establishment of a state examining board, which was to give certificates of efficiency to schoolmasters. No one was to be allowed to teach in an endowed school without holding such a certificate of competency, such certificates being also obtainable on a similar test by teachers in private schools. This part of the bill, however, was abandoned at an early stage. Its shipwreck marked the failure of the English middle class to organize secondary education upon German lines. Had the central authority of the State been armed in 1869, as Forster (*q.v.*) proposed, with this regulative power over the qualifications of teachers in secondary schools, secondary education would have been effectively organized from its base before the State undertook the great reform of elementary education. The secondary school teaching profession would have been established under government sanction, and would probably ere now have formed a branch of the Civil Service.

Higher grade schools, serving as a crown to the elementary schools, would have been established throughout the country upon a systematic plan, instead of being left to spring up sporadically and without distinct recognition in those cities in which the energy of the school boards and the weakness of conservative opposition made such somewhat irregular developments of the elementary schools practicable and popular. In the proposals of this part of Forster's bill we may trace the influence of his brother-in-law, Matthew Arnold. But the whole future of English education was changed by its abandonment. What remained of it, however, was sufficient to set going movements of reform which, when English local government was organized in 1888, quickly developed under the influence of the new local authorities. It is a question whether, if by an energetic propaganda Mr. Gladstone had prepared the public mind for the Endowed Schools Bill in its original form, opinion would have been found ripe to carry it in its entirety. As it was, the bill, even in its truncated form was in advance of public opinion. Aristocratic conservative influences and the suspicions of democracy were both adverse to the reorganization of secondary education under the authority of the State, both instinctively feeling that this step, if then taken, would have immensely fortified the position of the middle classes. But the latter showed themselves lethargic in their own interest, unimaginative in educational policy, distrustful of government action and (not a little to their credit) more concerned to help the poor and the unenfranchised than, by a long-sighted measure of self-preservation, to protect their own class interests in the State. It is not clear how far Forster himself realized the magnitude of the issues which turned upon the mutilation of his own bill.

Other aspects of this act and its relation to the development of English education in general are treated in the articles on ENGLAND, EDUCATION IN; GRAMMAR SCHOOL AND PARLIAMENTARY COMMISSIONS IN EDUCATION.

BALFOUR, GRAHAM. *Educational Systems of Great Britain and Ireland.* (Oxford, 1803.)

**ENDOWMENT OF COLLEGES AND UNIVERSITIES.**—See UNIVERSITIES AND COLLEGES, ENDOWMENT OF.

**ENDOWMENTS, EDUCATIONAL.**—Ancient.—Education was connected with endowments and has been largely dependent on them ever since, in B.C. 347, Plato devised his house and garden near the Academy, a suburban gymnasium called after the local hero, Academicus, in which he used to walk, talk, and teach, to his pupil and successor as a teacher, Speusippus. This house became an endowed college, and grew gradually richer from fresh endowments through its long life of 876 years,

till A.D. 529, when, with all other endowments of the University of Athens (*q.v.*), it was disestablished and disendowed by the Emperor Justinian as a pagan and anti-Christian propaganda. At Alexandria, Ptolemy Soter and his son Philadelphus about 300 B.C. founded and endowed the Museum, the temple of the Muses, sarcastically dubbed by the wits "the hencoop of the Muses" because of the large contingent of scholars and professors who were lodged and boarded there and paid substantial stipends. Endowments thus began with university or tertiary education. It is not till the Roman Empire was more than a century old that there is evidence of any endowments for secondary education. Quintilian (*q.v.*) is the first endowed schoolmaster recorded, and he is therefore said by St. Jerome (*q.v.*) to have kept the first "public school," because he received a stipend from the Emperor. But the first endowed school, in the sense of an endowment given by an individual with a view to defray part of the cost of the education to the parents, was that founded by Pliny the Younger at his native place, Como. In a letter to the historian Tacitus he says that he found a Como boy being sent to school at Milan, because there was no teacher at Como. He lectured the parents on the "small additional expense" a day school at Como would be compared to the cost of boarding boys at Milan. He gave sufficient endowments to find a third of the cost, and would have given more had he not been afraid of pauperizing the parents, and that "such an endowment might be corrupted to private interests, which he saw happen in many places where teachers were hired out of public funds." The Emperor, Antoninus Pius (138-63 A.D.), is said to have established offices and salaries (*honores et salaria*) for the rhetoric schools throughout the provinces, and Alexander Severus (221-235 A.D.) added exhibition endowments for poor boys, with the limitation *modo ingenuos*, so long as they were free-born. The Emperor Gratian in 376 A.D. made the municipalities provide endowments "out of the rates," and fixed a tariff. The rhetoric schoolmaster was to have twenty-four *annonae*, an *annona* being a year's living wage of a workingman; and the grammar schoolmaster half that. But at Trier, or Trèves, then the capital of the Western Empire, the rhetoric master was to have thirty, the Latin grammar master twenty, and the Greek grammar master, with the significant condition, "if one can be found," twelve *annonae* (*Cod. Theod.* xiii, 3, 11). In Gaul, in the fifth century, the invasions of the barbarians, the Burgundians, and Visigoths, swept away the municipal schools and the municipal institutions. When the invaders settled down, education, with other institutions, was no longer under the municipalities, the citizens, but under the bishops. (See BISHOPS' SCHOOLS.)

**England.**—In England the Saxon invasion had destroyed not only the Roman Empire, but whatever remained of the Roman, that is, the Christian, religion, and whatever churches and schools may have existed, with the Romans or Brito-Romans who, more or less, professed it. Consequently in England, when education begins again with St. Augustine of Canterbury (*q.v.*), it begins as an exotic education, and therefore in endowed schools. The schoolmasters were officers of the bishops, and endowed as part of the Church by the kings. In 598 Ethelbert of Kent, being baptized, "did not defer granting to his teachers a place befitting the dignity of their seat in Canterbury, his metropolis, and at the same time conferring on them necessary possessions of various kinds." Thence in 631 Sigebert, king of the East English, obtained masters and ushers, when he in turn, "with the assistance of Bishop Felix, whom he had obtained from Kent, set up a school in which boys might be taught grammar," as he had seen well ordered as an exile in Gaul, where he had been baptized. So too at York, a century later, education was endowed, being not only under the patronage of, but actually given by, the endowed archbishops themselves, Egbert (*q.v.*) and Albert or Ethelbert (*q.v.*). The first quasi-independent endowment of the school took place when, on the death of Albert, one of his pupils, Eaubald, became archbishop, and Alcuin schoolmaster. But the schoolmaster, though he became a separate cathedral officer, was maintained and lived, like the rest of the clerks or canons, as one only of the retinue of the bishop, maintained out of the general cathedral or episcopal revenues. These were not separated for another three or four hundred years, the bishop taking the bulk of the endowments as his own, leaving a lesser portion for the chapter. The eleventh and twelfth centuries saw this change take place. At York Thomas I, the first Norman archbishop separately endowed the schoolmaster (*Magister Scholarum*) about 1075. The Dean, and the Precentor, who looked after the Song School, were not separately endowed till 1090. At St. Paul's, London, a separate endowment was first given to the schoolmaster, (c. 1111.) when, by a deed still extant, the bishop gave him and annexed to his office a house by the Bell Tower and (c. 1127) granted the next master land at Fulham and the tithes of two churches near London. The schoolmaster was, however, not wholly maintained by the endowment, as in 1138 he obtained from the acting bishop a writ asserting his right to a monopoly of school keeping in London. In 1139 King Stephen endowed Salisbury School with three livings in Hampshire and their dependent chapels—an endowment of precisely the same kind as was given to Winchester and other schools up to the Reformation, and indeed up to the seventeenth century.

In 1179 an attempt was made to provide by general ecclesiastical law for the endowment of all cathedral schools, at least; Canon 18 of the Lateran Council of that year ordering that a competent benefice should be provided in every cathedral church for a master to teach the clerks of the church and all poor scholars gratis. It was probably in obedience to this canon that (c. 1181), Archbishop Roger of York endowed the school of York with £5 a year, payable out of the Rome-penny or Peter's pence, due to the Pope, and the synodical fees, due to the archbishop, of his three archdeaconries. Probably also this was the cause of the further endowment of St. Paul's School, London, in 1198, the bishop finding the endowments before given so scanty that the emolument of the mastership was little more than nominal, and giving it the tithes of Fulham, where the bishop's chief manor-house was and is, and 186 acres of land in various places near London.

About 1180, one of the earliest exhibition endowments was given for schoolboys at Durham. (See EXHIBITIONS.) About the same time Bury St. Edmund's School was endowed by the Abbot Sampson of Carlyle's *Past and Present* with a stone house, which he bought cheap from the Jews expelled from Bury, and with half a rectory, producing £5 a year; which seems to be a rich endowment for that time.

In 1215 the separation effected by another Lateran Council between the theological and grammar schools of the cathedrals and ancient collegiate churches, like Beverley, acted practically as a measure of disendowment for the latter, as the schoolmaster, who now took the title of Chancellor and confined himself to theology, took all the old endowments. The grammar schoolmaster was his deputy, and was paid a very small stipend by him, generally about £2 a year, as at Southwell Minster. The grammar schoolmaster was, however, further endowed by being given a vicar choralship or a chantry priesthood, or both, as at Lincoln; but he had no legal title to either, with the result that at Salisbury and at Wells the grammar schools came to be treated not only as unendowed, but as not even being a legal charge on the cathedral endowments at all in the eighteenth century, and perished for lack of them. Elsewhere this result was prevented by later endowments. Thus at St. Paul's, London, the school was saved by Colet's magnificent new endowment given in 1510, and at York by the annexation to the school of the endowments of a hospital for poor priests by Cardinal Pole in 1557.

It is a remarkable testimony to the thirst for learning and the felt want of higher or university education in the eleventh and thirteenth centuries that none of the universities were endowed. Paris, Bologna, Oxford, Cambridge, all grew up spontaneously like the philosophical schools of Hellas, to answer the demand of

those who were prepared to pay for being taught, and, being mostly grown-up, or nearly so, were able to pay. The two old universities of England, even now, possess as such next to no endowments. The chief endowments there are those of colleges (*q.v.*), beginning with that of Merton at Oxford in 1264, and of Peterhouse at Cambridge in 1280, and of professorships beginning with those of the Lady Margaret, mother of Henry VII, in 1503.

Secondary education was always endowed, because all the early grammar schools formed part of the foundation of collegiate churches, the foundations of which were numerous before the Conquest and up to about 1150, and began again with renewed vigor about 1260. In the twelfth and first half of the thirteenth century, in those places where the schools were severed from collegiate churches, by the colleges being suppressed and their endowments given to monasteries, the earliest separate grammar school endowments are traceable. We have already noted this at Bury St. Edmund's in the twelfth century. At Derby, where the school was transferred from the collegiate church to a new monastery about 1150, a successful townsman, Walkelin, and his wife, Goda, came to the help of the school by giving their merchant's shop and some eight acres of land as an endowment, while their own house was to become a school and boarding house for the master and his clerks forever. At Colchester in Essex, a deed of 1206 gives evidence that the school there was endowed at least with a building, and perhaps with lands as well. At St. Alban's, Master Richard of Nantes, himself apparently the schoolmaster, endowed the school with a house in the town about the year 1286, the schoolmaster being bound to admit sixteen of the poorest scholars free in return for being thus relieved from hiring a house. His only other endowment was £1 6s. 8d. a year from the Almoner of the monastery for teaching the (probably) thirteen Almonry (*q.v.*) boys, and this was not earlier than 1330. At Pontefract a custom, already old in 1267, prescribed the partial endowment of the school by the loaves founded by St. Nicholas Hospital for its boys, as St. Cross Hospital at Winchester provided dinners daily for thirteen boys from its otherwise unendowed high school. In 1332 an endowment was given by Bishop Stapleton of Exeter for thirteen boys of the grammar school there in the shape of board, lodging, clothing, and private tuition in St. John's Hospital, which, after the Reformation, became wholly converted into an educational endowment. The Burghersh Chantry at Lincoln, founded in 1345, similarly provided lodging, board, and clothing for a few boys attending the grammar school there. Mountney's chantry at Chelmsford in Essex, founded in 1375, was a school endowment as well, the chantry priest being also bound to keep a grammar school; and was continued at the Dissolution in consequence.

Though there was no difference in the form of the foundation and the nature of its endowment between Winchester College and previous educational endowments of collegiate churches and others, yet an immense impetus to school endowments was undoubtedly given by William of Wykeham's foundation of that college in 1382, as it provided not only for the maintenance and pay of the schoolmasters, but for the maintenance and free education of the seventy scholars who with their warden formed the college itself. In 1384 Wykeham's foundation deed was imitated on the very much smaller scale of a master and two boys at Wotton-under-Edge by Lady Berkeley (*q.v.*) and in 1393 on precisely the same scale at Bredgar, Kent, by a body of subscribers. It is also probable that the endowment of the schoolmasters at Maldon and Rayleigh in Essex, both in 1388, by the guilds there, was also suggested by Winchester. The large number of chantries and guilds licensed about this time, which at the Dissolution were found to be maintaining grammar schools out of their endowments, may not, however, be due so much to the impulse given by Wykeham as to the registration and formal legalization of existing unlicensed institutions, made known to the authorities through the return of guilds required by the Crown in consequence of the Peasants' Revolt, in 1389. The endowment in 1412 of Durham Grammar School and another school at Middleton in Lancashire, his native place, by Thomas Langley, Bishop of Durham, is, however, a distinct following of Wykeham. So also was the incorporation of the previously unendowed grammar school at Higham Ferrers in Northamptonshire by Archbishop Chicheley, one of the earliest scholars of Winchester, in 1425, as part of his college, a smaller Winchester. Chicheley also followed Wykeham in utilizing the dissolved Alien Priors (*q.v.*) as a means of providing cheap endowments for education. The Alien Priors were religious houses in England, attached and paying rent to foreign houses abroad. They were mostly purely monastic, and did nothing for education. They were suppressed on political grounds to prevent their contributions to French houses, being used by the French as sinews of war against England. Some of them were made denizen, that is, naturalized as English monasteries and severing connection with the foreign head. William of Wykeham set the example of buying them up to serve as part of the endowment for his new colleges of Winchester and New College, Oxford. Henry V contemplated founding a great college of the Seven Sciences at Oxford out of their spoils. Archbishop Chicheley both himself bought several from the king to help to endow his two colleges of Higham Ferrers and All Souls at Oxford, and he with Beckington suggested to Henry VI their application to Eton College and King's

College, Cambridge, the endowments of which were larger than that of any other college or school in the kingdom, and almost entirely consisted of Alien Priors. It is curious that those historians who denounce Henry VIII in unmeasured terms for appropriating monastic endowments to education and other public purposes have nothing but praise for the sainted Henry VI for setting the example on a large scale. The ready mine of the Alien Priors heightened the standard of endowment. While Merton in 1274 thought £2 13s. 4d. a year ample for the scholar fellows of Merton College, and Wykeham in 1382 to 1400 provided sufficient to give the warden of Winchester £20 a year, the headmaster £10 a year and the fellows £5 a year, Henry VI raised the pay to £50 a year for the provost, £16 a year for the headmaster, and £7 a year for the fellows. So at St. Anthony's School in Threadneedle Street, London, a hospital served by alien canons regular was converted into a hospital served by secular clerks, with a school attached, in which the master got £16 a year.

The flow of endowments to education, stopped for a while during the period of depression caused by the disastrous wars in France and the Wars of the Roses in England, was renewed with unabated force from 1475 onwards. The endowment of Magdalen College and the two schools attached to it, at Oxford and at Wainfleet in Lincolnshire, by William Wayneflete, rivaled those of Wykeham and of Henry VI himself. The colleges of Aeaster and Rotherham in Yorkshire by two successive chancellor bishops gave an enlarged scope to endowments by putting writing and arithmetic schools on the same footing as grammar and song or reading schools, as integral parts of the collegiate establishments, instead of being relegated to parish clerks who eked out their scanty clerical pay by teaching. The successful merchant, too, now came in to rival the successful churchman as a giver of endowments. One lord mayor after another, from Sir Edmund Shaw at Stockport in 1487 to Sir Stephen Jenyns at Wolverhampton in 1508, testified alike to the growth of commerce and the spread of education, accompanied by a desire to strengthen it by endowments placed under the government, not of ecclesiastics, but of laymen, the City Companies.

Meanwhile, a new mine of endowment was opened up when Wayneflete obtained the suppression of Selborne Priory, Hants, on account of its financial and moral failings, to endow Magdalen College at Oxford, thus applying the principle of the suppression of Alien Priors to those of home growth. This example was followed on a large scale by the pious Lady Margaret Tudor, mother of Henry VII, advised and assisted by Bishop Fisher, in the suppression of St. Radegund's nunnery to found Jesus College in 1497, and St. John's Hospital, kept by regular canons, to found St.

John's College, Cambridge, in 1511. Cardinal Wolsey carried the precedent still further, and threw all former foundations into the shade, by the wholesale suppression of monasteries under Papal bulls to find endowments for his two great Cardinal colleges at Ipswich and at Oxford in 1527. The precedent was not lost upon Henry VIII, who found ample endowments for education in the possessions of the dissolved monasteries. With them he founded cathedral grammar schools (see CATHEDRAL SCHOOLS), with large numbers of endowed scholars, ranging from fifty at Canterbury to twenty at Peterborough, and with endowments of not less than £20 to £30 to the headmaster, and for his two great colleges, Christ Church at Oxford, a reorganization of Wolsey's College, and Trinity, Cambridge. Unfortunately, while the two colleges are still the greatest, or among the greatest, endowed institutions in the country, the schools, since the schoolmasters were not members of the governing body, have been stinted and starved, and in consequence long eclipsed by foundations originally on a very much smaller basis.

The further progress of the Reformation in England under Edward VI was marked by a measure which, though not so intended, operated as a great disendowment of education, — the act for the dissolution of colleges and chantries in 1548. Provision was made in this act for the continuance of grammar schools and their reëndowment out of the dissolved chantries. But, as a fact, owing to the sale of the endowments and the failure to carry out the provision for reëndowment, except in some thirty cases, among which Sedbergh, in Yorkshire, and Birmingham are the most conspicuous, the measure resulted in the gradual decay from lack of endowment of the greater number of the schools. So, instead of Edward VI (*q.v.*) being the founder, as commonly supposed, he was in great part the destroyer or depraver of endowed schools. Queen Elizabeth (*q.v.*) has sometimes been represented as having given many endowments to education, but a careful inquiry has shown that a very large number of the schools professing to be founded by her or in her time were merely restorations or enlargements of pre-Edwardian schools.

The certificates of the commissioners under the Chantries Act have been only partially preserved; those of several counties, notably Norfolk and Suffolk, two of the most populous and prosperous counties in England at the time, are wholly missing. But they show (see REFORMATION AND EDUCATION) 259 endowed grammar or secondary schools then existing. It is an underestimate to put the total number at 300, because, wherever close local research is brought to bear in old towns, a grammar school almost invariably appears. (See CHANTRY SCHOOLS.)

The same is largely true of the schools re-

puted to be founded by James I, or in his time, such as Evesham in Worcestershire and Otley in Yorkshire, both called Prince Henry's Schools, in honor of his eldest son, the Prince of Wales. The statistics given by the Schools Inquiry Commission as to the endowing of new schools in all these reigns, which has been quoted, even in this *Cyclopædia*, as authoritative, must be received with considerable skepticism and require to be subjected to close scrutiny in connection with local records before they can be accepted. The most curious instance of a really new foundation on the old model is that of the College of God's Gift at Dulwich, founded by the successful actor, Edward Alleyn (*q.v.*), in 1616, out of his professional profits. In close imitation of Winchester and Eton, it provided for a warden and three fellow masters and twelve scholars, but owing to lack of endowment was a failure for 300 years.

The bulk of endowments from the time of Charles I flowed to elementary education. Many of the schools were nominally grammar schools because the authorities seem to have been opposed to granting licenses in mortmain for anything else; but Latin is often mentioned *pro forma*, the master being directed to teach English grammar, writing, and arithmetic, and "Latin, if required," which it increasingly was not. During the Commonwealth (*q.v.*), when bishops and deans and chapters were dissolved, a serious attempt was made to apply their endowments to the augmentation of old and the foundation of new colleges, notably Durham, and to schools, especially in the North, the West, and in Wales, and among them largely to elementary schools. These all perished, and the endowments were restored to ecclesiastical purposes at the Restoration in 1660. For nearly 200 years not a single college was endowed at Cambridge, and only one at Oxford, and scarcely a single grammar school. But every year saw endowments given for new elementary schools, and from 1699 to 1800 for what were called *par excellence* charity schools (though all endowed schools are strictly and in law charity schools), schools in which children taken from the lowest classes were boarded and taught, the girls for domestic service, the boys for apprenticeship. (See CHARITY SCHOOLS.)

In 1828 a new series of endowments, by subscriptions from numerous subscribers rather than by single benefactors, for higher education of a quasi-university type, began with University College (undenominational), and King's College (Church of England), London, in 1828. This was followed in 1831 by the endowment of Durham University (*q.v.*) out of the revenues of Durham Cathedral, thus reverting to and justifying the action of the Commonwealth in 1637.

About 1848 a revival began in the endowment of grammar or "public" schools, second-

ary schools, chiefly boarding schools for the middle and lower-middle classes, commonly called colleges (*q.v.*), such as Cheltenham and Marlborough, Bradfield and Radley, Haileybury and Clifton. The reformation of the old schools by the Public Schools and Endowed Schools and Charity Commissioners produced a great flood of new endowments, in many cases amounting to refoundation, though these new endowments are generally given for particular objects, such as exhibitions, scholarships, and prizes for proficiency in particular subjects. In fact, more endowments have been given for this class of secondary education in the half century since 1850 than in the whole 250 years before. Meanwhile, the more and more complete transfer to the State and to local authorities of the control and financing of elementary schools since the Elementary Education Act, 1870, has resulted in an almost absolute cessation of endowments for that purpose. On the other hand, there had been a new large flow of endowments to university colleges, many of them now endowed into universities, beginning with Owens College, Manchester, 1851-1870, Mason College, Birmingham, 1870, Aberystwyth, 1872, Bristol, Leeds, Sheffield, Nottingham (not yet a university), Bangor, and Cardiff, which with Aberystwyth form the University of Wales. Technical colleges and schools have sprung out of or have been endowed in connection with the new universities.

From 1848 endowments have been poured on girls' and women's education, beginning with Queen's College, and Bedford College, London, in the following year; while there are now two endowed women's colleges at each of the ancient universities, Girton and Newnham at Cambridge, Somerville and Lady Margaret Hall at Oxford. Girls have also claimed, and in many cases been allowed, a share in the old grammar school endowments by the endowment of girls' schools out of their surplus; while new girls' schools have sprung up everywhere, which beginning in voluntary effort, like those of the Girls' Public Day Schools Company (*q.v.*), have been since converted into endowed schools. Such is the history of endowments for education in England.

A. F. L.

**Theory of Endowments.**—As to the philosophy of endowments, much has been said against them. One of the earliest important discussion of the question is found in Turgot's article on *Fondation*, contributed to the *Encyclopédie* in 1757. Here all types of endowments, religious, philanthropic, and educational, are considered. That Turgot did not look with favor on endowments is obvious from a sentence which comes early in the article: "A founder is a man who desires the effect of his own will to endure forever." However enlightened a founder may be, the aim of the endowment is to provide for an object which in

all probability is limited in its effects, and not necessarily of general interest. "To enable a large number of men to live gratuitously is to subsidize idleness," for even though an endowment may in its origin be highly laudable, this spirit soon disappears, routine administration and regulations enter in, and it becomes impossible to fulfill the purpose of the founder. Frequently the prescriptions are so very narrow that it is easier to establish an entirely new foundation. But the chief objection against foundations in perpetuity is based on the fact that social needs change, and social institutions must admit of plasticity. Hence he claims it as an incontestable right of government on a basis of public utility "to dispose of old foundations, to extend their funds to new rights, or, better still, to suppress them altogether." "Are men powerfully interested in that good which you would procure for them? Leave them free to attain it; this is the great, the only principle."

The same *laissez-faire* attitude, with some qualifications, is adopted by Adam Smith (*q.v.*). With Turgot he holds that a position which is endowed is removed from competition and the consequent exertions, since the incumbent is already provided for, and is independent of success or reputation. So far as scholarships and exhibitions are concerned, colleges which provide these can always secure students without the necessity of competition with other colleges. Those parts of education which are not provided for by endowments are generally the best taught. Hence leave education to the general working of supply and demand, "were there no public institutions for education, no science would be taught for which there was not some demand." Dr. Chalmers (*q.v.*), in an essay *On the Use and Abuse of Literary and Ecclesiastical Endowments* (1827), denies the analogy between free trade in merchandise and learning; appetite for food may be a strong stimulus, but desire for education is not so potent. Accordingly endowments have their uses as setting standards and inviting coöperation and imitation. Further, unlike Smith, Chalmers argues that endowments are of great value in maintaining chairs in subjects which are important but not popular, holding that, while hunger does create a desire for food, a desire for learning by no means follows from ignorance. A somewhat similar view was held by John Stuart Mill, who was of the opinion that endowments could be usefully employed in promoting experimentation for purposes which do not at first commend themselves to general approval. Rev. R. J. Bryce, on the other hand, criticized before the National Association for the Promotion of Social Science (1860) both of the preceding views, and recommends the introduction of compulsory education, the training of teachers, and the proper use of existing endowments for the education of the poor and not

as bounties for the rich. As early as 1838, George Long, in the publications of the Central Society (see EDUCATIONAL ASSOCIATIONS), had dealt with the history of educational endowments in England. He was of the opinion that, while the intention of donors should be followed, so far as possible, the legislature should have power to remedy defects when such intentions are not in accord with social progress. Long cites numerous cases from the law-courts which prove how a narrow interpretation of endowments has retarded education. The best known instance is, of course, the case of the Leeds Grammar School, where Lord Eldon (*q.v.*) refused to allow the introduction of modern subjects, on the ground that the donor had intended to found a "grammar" school only. Finally Sir Joshua Fitch (*q.v.*), who could speak with authority after examining a considerable number of endowed schools prior to the Endowed Schools Act (*q.v.*), contended that the public should have the same rights as a private legatee, and suggests as conditions under which endowments might be accepted that the object has worth, that the mode of attaining it is not too rigidly prescribed, that it is managed by a broad-minded governing body, that the State must supervise and make amendments where necessary for the benefit of the public.

Robert Lowe, Vice-President of the Committee of Council on Education, in 1865 stated emphatically that he had the poorest opinion of endowments, and was not sure that he would not abolish all educational endowments altogether. He based his objections on the ground that they give a premium to continue teaching things after the spirit of the age had got beyond them. This objection is in principle the same as that to endowments for any purpose, viz. that they are a vicious exception to the ordinary law, by enabling the dead-hand to retain its power over property which belongs to the living, and to dictate for all time in virtue of a transient possession to what purpose property, which only retains its value by the work of the living, shall be applied. In all countries, even in China, a law of mortmain to prevent land from falling into the dead-hand has at some time or other been found necessary and attempted. In principle the law which enables any one "to endow a college or a cat" forever during their lives is equally irreconcilable with the law of property as that which enables them to do so after death. But furthermore endowments by will, given, as many of them have been given, to spite relations who have had a reasonable expectation of succession, or by way of expiation of evil done in life, are even more in breach of the ordinary law and theory of property, as they involve no effort or sacrifice on the part of the giver, and are generally given with less forethought or planning of results. There does not appear to be any answer to the theoretical objection to en-

dowments. But the practice of all civilized nations, and the public opinion in favor of the "pious founder," founded on admiration of particular endowments for particular objects of which they approve, perennially forgetful that there are many more endowments of objects of which they disapprove, have elevated the giving of endowments into an object of admiration. There is even a sort of competition among the rich, encouraged by the newspaper press, to attain posthumous merit as benefactors by endowments out of possessions which they cannot take with them. In view of the prejudice that exists in favor of this vicarious piety, it is hopeless to expect a real law of mortmain. In England, however, since the passing of the Andover Schools Act, 1869, the Board of Education Act, 1899, and the Education Act, 1902, the powers of the State to revise endowments have to a considerable extent, as regards secondary education, lessened the evils pointed out by Robert Lowe. The stereotyping of subjects and methods of instruction, the exclusion of new ideas and new subjects, are less rigorous. But in the sphere of higher education the difficulty of revision is as great as ever. The universities and colleges still require a *deus ex machina*, in the shape of a Parliamentary Commission, to effect reform. Experience has shown that it is hopeless to expect it from those who are themselves endowed for specific purposes, however obsolete. An absolute and uncontrolled power to the Board of Education of revising all educational endowments more than forty years old is necessary if endowments are not to continue to be mischievous by continuing to encourage the teaching of subjects not according to the wishes and wants of the living parent and child, but according to the fancies and prejudices of the past. (See also PHILANTHROPY, EDUCATIONAL.)

A. F. L. and I. L. K.

**United States.**— One of the earliest indications of educational interest in colonial history is the giving of endowments to found or to assist educational institutions. In no respect is the transference of English custom and the European attitude toward education better evidenced. And the giving of money or other forms of wealth for education is found in connection with every type of educational institution, elementary, secondary, and higher.

As early as 1618 both the government and public-spirited individuals had offered endowments for a college at Henrico. The private contributions had been collected by the bishops of the Church of England at the "command" of the King during the two years previous. The company itself set aside 10,000 acres of land. Through various circumstances, chiefly an Indian massacre, this movement came to nought. The so-called "East India" school was endowed from a collection of £70 taken on a ship of the East India Company, supplemented later by other collections. In 1643

an endowment for a free school was given by Benjamin Simms, and still later in the century came the endowments for the first college, William and Mary (*q.v.*), contributed to by private subscription as well as by royalty. (See COLONIAL PERIOD IN AMERICAN EDUCATION; VIRGINIA.)

In Massachusetts the history is similar. The most notable endowment was the gift of John Harvard (*q.v.*) of £728 and his library to the institution which bears his name. The great number of private gifts which followed were not so much for the purpose of creating an endowment as for current needs, though the two purposes were not always kept distinct. The most immediate needs were land and buildings, and these could hardly be distinguished from endowments.

The early towns of New England frequently, if not usually, made grants of lands to the town school to serve as endowments. But when land was to be had almost for the asking, it was not very productive as an endowment, so that it was not until late in the seventeenth or early in the eighteenth century that such grants became of much profit. Endowments are found for only a few, and these not of great amount. Boston received a legacy of £10 in 1655; Dedham of £60 in 1680, and £100 in 1749; Brooklyn of £308, "half Johannes," in 1762, Newbury of £100 in 1779. In a similar way, grants of land were frequently made. Most of these were to the Latin School, but sometimes the two schools were not distinct. By the middle of the eighteenth century the support of both Latin and elementary schools had become public in practically all of the Massachusetts towns.

During the latter part of the eighteenth century a new type of school sprang up which called forth endowment gifts at first. These were the academies. These endowments began with the gifts of the Phillips family to the academies at Andover and Exeter which bear their name. (See ACADEMIES.) Again, the willingness of the public to support these or similar institutions destroyed the need for private endowment. The various states came to the support of academies in great number, and high schools developed after 1821. Only a few of the academies accumulated any considerable endowment funds, and most of those developed from secondary schools into colleges.

It is the college which in America has attracted the vast amount of philanthropic gifts to education. The entire system of four to five hundred institutions of accepted collegiate standing, with the almost similar number bearing the name but not attaining to the full standard of collegiate work, are most of them founded by private gifts, and all which have any permanency, with the exception of a few of the state institutions, are supported by endowments made as charitable gifts. The

development of this phase of educational support is one of the most striking phases of American educational history. It will be discussed more fully under the title, PHILANTHROPY, EDUCATIONAL (*q.v.*). The importance of endowments in the history and life of particular institutions is indicated in the articles on the various colleges and universities. The general significance and extent of endowments is discussed in the articles on COLLEGES, AMERICAN; and UNIVERSITIES, ENDOWED AMERICAN.

**ENGLAND, EDUCATION IN.** — **History.**—The history of English education is typical of the history of English institutions. It has been built up by a long series of experiments and compromises; it has been guided by a sense of the practical, and has been a response to the need of the moment rather than the result of theorizing, or a well-considered plan and purpose. Hence the history of English education is the history of movements or of forces which have determined its evolution. A national system of education England never had until the close of the nineteenth century. Few nations show the influence of so many different forces in their educational history as may be recognized in that of England,—the Church, the State, economic conditions, private enterprise, philanthropic endeavor, educational theories,—all have contributed some tradition to what is gradually developing into a well defined system. This being so, it would be difficult within the limits of one article to do more than refer to the numerous topics which deal more fully with the different phases of that development. This article is concerned mainly with the more recent development of the nineteenth century, in which the State has more and more attempted to weld the different forces into a system. While a division is made into periods, this is only done for convenience in grouping, for no one type is

necessarily confined within the limits of the period in which it is placed.

*Medieval Period.*—While some traces of the earliest dawn of education in England is given in the article on Druids and Education, and in Roman Imperial Education in Great Britain, the characteristic medieval influence is that of the Church, as may be seen by reference to the different types of schools of the period; Almonry Schools, Cathedral Schools, Chancellor's Schools, Chantry Schools, Chorister Schools, Cloister Schools, Collegiate Church Schools, Convent Schools, York School, Jarroo School. Other aspects of medieval education are treated in the articles on the Alien Priors; Boy Bishop; Benefit of Clergy; Bible in the Schools; Church Attendance of Pupils; Chancellor; Canon Law in Education; Cloveshoo, Council of; Clerk; Magister Scholarum; Monasticism; Teachers, Licensing of; Universities; Scholasticism. The articles on the leading educators will also contribute some suggestions on the education of their period, as Augustine of Canterbury; Adrian; Alfred; Ælfrie; Albert of York; Aldhelm; Biscop; Bede; Egbert of York; Patriek, St., and others. The secular or political influences on medieval English education are reflected in the articles on Anglo-Saxon Schools; Anglo-Norman Dialect; Anglo-Norman Schoolbooks; Bibleworth; Black Death and Education; College; Common Law and Education; Common Master of the Town; Chivalric Education; Gentry and Nobles, Education of; Guilds and Education; Henry II; Henry VI; Eton College; Lollards' Schools; Manor Schools; Fees; Punishment, Corporal; Song Schools; School. The main features are contained in the summary article Middle Ages, Education in the.

*Renaissance and Reformation.*—The two movements coalesce in English education, and are marked mainly by the movements in secondary education which are treated under Henry VIII; Edward VI; Elizabethan Education; Endowments; Free Schools; Fees; Grammar Schools; Gentry and Nobles, Education of; Reformation and Education. The Renaissance aspect is covered mainly in the biographies of the remarkably large number of educators and others who interested themselves in the theory and practice of education. The most notable only of these can be mentioned here; Ascham; Baret; Brinsley; Colet; Coote; Dury; Eliot; Gilbert, Sir H.; Hoole; Kuox, John; Lily; Mulcaster; Udall. Further the following articles may be consulted for school practice; Barring out the Teacher; Cock-fighting; Declamation; Dictamen; Disputation; Dormitories; Fagging; Usher; Manners, Teaching of; Greek, Hebrew, Latin, and other school subjects. State intervention is treated in the articles on Apprenticeship and Education; Dissenters in Education; Poor Law and Education; and Teachers, Licensing of.

*Seventeenth and Eighteenth Centuries.* — The first of these two periods is marked by a struggle between the Established Church and dissenting bodies, the former insisting on a monopoly of education. This phase is brought out in the articles on Academies, Nonconformist; Dissenters and Education; Common Law in English Education; Commonwealth in England and Education. The realistic influences of this period are reflected in the articles on Bacon, Francis; Boyle, Robert; Royal Society; Eachard; Hartlib, S.; Milton, J.; Locke, J. The combination of religious and philanthropic endeavor with education may be traced in the articles on Baxter, Richard; Bray, T; Charity Schools; Charitable Trusts for Education; Circulating Charity Schools; Gouge, Thomas; Society for the Promotion of Christian Knowledge; Society for the Propagation of the Gospel; Wales, Education in. The course of education in the next century is treated in the articles on Eighteenth Century and Education; and in the biographies such as Burke; Blackstone; Chesterfield; Cowley; Cowper; Day; Defoe; Edgeworth, R. L., and Mary; Goldsmith; Gray; Hume; Mandeville; Pope; Smith, Adam.

*Nineteenth Century.* — While the main trend of the nineteenth-century movement in English education is treated in outline in the present article, especially from the date of the first state grant, the following articles may be read as supplements on other issues. The monitorial system is treated both separately and also under Bell; Lancaster; British and Foreign School Society; National Society; Borough Road Training College. Different types of education are dealt with in the following topics: Adults, Education of; Apprenticeship and Education; Boys' Brigades; Continuation Schools; Evening Schools; Technical Education; Preparatory Schools; Public Schools; Grammar Schools; Endowed Schools Act; and Eton, Harrow, St. Paul's, etc. Higher education will be found under the general article Universities, and under the separate universities, as Oxford, Cambridge, London, Manchester, etc; University Extension; Workingmen's Colleges; Degrees; Tripos; Wranglers, etc. Administrative aspects are treated under Apportionment of School Funds; Attendance, Compulsory; Cost of Education; Cockerton Judgment; Cowper-Temple Clause; Education Committee of the Privy Council; Lords, House of, and Education; Examinations; Official State Publications of Education; Child Labor; Childhood, Legislation for Conservation and Protection of; State Intervention; School Board System. For this, as well as the preceding centuries, see also Poor Law and Education. Questions relating to teachers are covered by the following topics: Certification of Teachers; Education, Academic Study of; Pensions; Pupil Teachers; Salaries; Teachers' Agencies; Teachers, Appointment of; Teach-

ers' Tenure; Teachers, Training of; Teachers' Voluntary Associations; Training Colleges. School practice is dealt with under Athletics; Examinations, and the various subjects of the curriculum; Holidays, School; Parents and Schools; Punishment, Corporal; Vacations, School, etc. The articles on Bible in the Schools; Moral Education; Nonconformists in Education; Religious Education; Sunday Schools, etc., deal with the field of religious education. The debt due from English education to foreign influences is traced in the two articles French Influences in English Education, and German Influences in English Education. Lastly the activity and contributions of English leaders to the recent educational development may be found under the biographical notices of Acland, Sir Thomas; Arnold, Matthew; Arnold, Thomas; Allen, William; Bain, Alexander; Beale, Dorothea; Buss, Francis M.; Bradley, George G.; Besant, Sir W.; Brougham, Lord; Clough, A. J.; Dickens, Charles; Faraday, Michael; Fawcett, Henry; Fielden, Sarah; Fitch, Sir Joshua; Forster, William E.; Galton, Sir Francis; Gladstone, William Ewart; Hamilton, Sir William; Hawtrey, Edward C.; Hill, Thomas Wright; Hogg, Quintin; Huxley, Thomas H.; Kay-Shuttleworth, Sir James; Kennedy, Benjamin H.; Laurie, Samuel S.; Lowe, Robert; Quick, Robert H.; Payne, Joseph; Pounds, John; Raikes, Robert; Russell, Lord John; Spencer, Herbert; Stanley, Edward G.; Walker, Frederick A.; Whewell, William; Whitbread Samuel; Wyse, Sir Thomas. Other topics, which are treated in more detail than is possible in the following account, are marked by a cross-reference.

**Development of a National System.** — The internal disorders of England brought about by the wresting of industry from its wonted grooves were aggravated in the early years of the nineteenth century by the struggle with Napoleon and the subsequent contest with America. These wars enriched the landowners and capitalists, but impoverished the poor, and increased their bitterness toward the rich and powerful. At the same time new conceptions of the functions of government which had been advocated by philosophical writers, by Adam Smith, by Bentham and Blackstone, and new doctrines, exemplified in particular by Robert Owen, founder of English socialism, began to take shape in reform measures urged upon Parliament and agitated in the press.

The Factory Act of 1802 marked the advent of Parliament as a controlling factor in the education of the industrial masses. By the sixth section of the act, provision for the instruction of young apprentices was made obligatory upon the master or mistress of such apprentices, and though persistently evaded by parents and employers the clause fixed an important precedent in English law. (See FACTORY SCHOOLS.) A simple bill to provide

schools where none existed, introduced by Mr. Whitbread (*q.v.*) in the House of Commons in 1807, was pared down to the smallest terms and then lost in the House of Lords. Eight years later the subject was renewed in the lower house by Mr. Brougham (*q.v.*), who waged the losing campaign with unflagging energy. His education bill, introduced in 1820, but foredoomed to failure, is of chief interest to-day as an index to the denominational forces which have stubbornly contended at every step in the progress of national education. The positive achievements of this brilliant leader were the commissions of inquiry whose appointment he secured; one, in 1816, on the state of popular education in the Metropolis; the second (1818) on endowed schools. The mass of information thus brought together and Brougham's personal appeals to popular opinion contributed powerfully to the final success of the cause for which he stood.

*The First Grant for Elementary Education.*—The passage of the reform bill in 1832, which greatly extended the franchise in England, awakened a new sense of peril from the ignorance of the masses, and in the following year (1833) the first Parliamentary grant, £20,000 (\$100,000) was made for elementary education. The money was applied solely to the erection of schoolhouses and in aid of private subscriptions for the purpose. Thus at length Lord Brougham's dictum, "The education of the people is a matter of vital concern," was wrought in English law and precedent. By the terms of the treasury minute adopted Aug. 30, 1833, assistance from the grant was only allowed upon satisfactory reports as to the application from either the National Society (*q.v.*) or the British and Foreign School Society (*q.v.*). For six years the two societies controlled the distribution of the grant, and down to 1870 their influence was paramount in shaping the spirit and methods of elementary education. Thus by its origin the national system acquired the main characteristics of the earlier voluntary systems. It inherited from them the monitorial expedient, which developed into the pupil-teacher system, and training colleges for teachers, with their dual relation to State and Church. Official regulations and an official inspectorate were, however, a constant reminder of the reserved power of the State in this growing interest.

The period from 1833 to 1870 was marked by the extension of government action through existing agencies. In 1839 the annual grant was increased to £30,000 (\$150,000), to be applied without restriction for purposes of elementary education; the same year a separate Committee of the Privy Council was appointed to take charge of grants voted by Parliament for education. In 1847 Roman Catholic and Wesleyan Associations were admitted to the benefit of the annual grant. In 1856 a Vice-President of the Committee of Council on

Education was appointed and made directly responsible to the House of Commons for the distribution of the sum voted by them for the promotion of education. The growing importance of the interest led in 1858 to the appointment of a Royal Commission (Duke of Newcastle's Commission) to inquire into the state of popular education in the country. The report of that Commission, presented in 1861, made many recommendations, but the only one of these that was put into immediate effect introduced into the system the evils of "payment upon results." Under the plan as embodied in the *Revised Code* (Mr. Lowe's), 1861, the amount of grant allowed a school, and, hence, the prospect and position of the teachers, were made dependent upon "the individual examination" of pupils.

While the government was holding thus firmly to a narrow system of state aid for education through the agency of private bodies, public opinion on the subject was making rapid advance, especially in the great centers of population. In Manchester a committee was organized to promote a general system of secular education in the county of Lancaster. This committee subsequently expanded into "The National Public School Association," which advocated secular schools supported by local taxes and managed by local committees throughout the kingdom. Later a similar movement was started in Birmingham, which expanded into the famous "League" and kept up the agitation for a secular system of free schools till 1877. The movement soon spread to every principal town in England. It was offset by the Manchester and Salford Committee, formed in the interests of state-aided denominational schools.

**Education Act of 1870.**—The electoral reform of 1868 and the sweeping Liberal majorities that followed caused the reopening of the education question in Parliament, and on the 17th of February, 1870, Mr. Forster's celebrated bill was presented to the House of Commons. It was a compromise measure, and so distinctly favorable to the denominational school system that it excited tremendous opposition in the ranks of the Liberals and a most acrimonious debate within the House itself. A deputation from the Birmingham League, headed by the chairman, Mr. Chamberlain, waited upon Premier Gladstone to protest against the measure; they were followed by the Welsh Educational Alliance. But in spite of opposition, the bill became law, and has formed the groundwork of all subsequent school legislation in England.

According to the statement of Mr. Forster in his speech presenting his bill, the state-aided system was educating at the time, "more or less imperfectly," 1,500,000 children. Many of these were mere infants; of the children between six and ten years of age it was estimated that 700,000 were in the aided schools, against

1,000,000 who were "neglected"; of those between ten and twelve, 250,000 were in the schools and 500,000 not accounted for.

In its original form the bill proposed that school boards in municipal districts should be elected by the town councils. Owing to the chaos of English local government, there were no suitable corresponding local authorities outside the municipal areas. Forster was therefore driven to propose that in nonmunicipal districts a new local authority, the school board, should, where deficiency in school accommodation compelled its formation, be elected by direct popular vote. It was originally proposed that the school boards should have power not only to establish, where necessary, schools under their own management, but to aid out of rates existing voluntary schools, on condition, however, that where such aid was given schools of all denominations should be regarded as having an equal claim to such assistance. The school boards were to be left perfectly free in their regulation of the religious teaching given in schools under their direct control.

In the course of Parliamentary discussion, often embittered and perilous to the government, the original framework of the bill was greatly changed. The municipal school board was abandoned. A new local authority elected *ad hoc* was in all cases to act as a school board. In the case of its own schools, the latter was forbidden, in the words of the Cowper-Temple clause, to allow "any religious catechism or religious formulary which is distinctive of any particular denomination" to be taught to the scholars. It might, if it so preferred, provide no religious instruction at all. The voluntary schools were disqualified from receiving any aid from rates, and were given an increased grant from the Parliamentary vote. Thus the bill set up in unstable equilibrium the new board schools and the voluntary schools as two parts of a dual system of elementary education. The idea of a municipal authority in elementary education could not be realized till the year 1902, when the working of the Local Government Act of 1888, had covered the whole country with a common type of local authority.

Mr. Forster's act was the real, though belated, beginning of the present organized system of national education in England. Something like it ought to have been passed forty, or even sixty, years earlier. English life has never recovered from this protracted delay in the systematic organization of public schools. One root cause of the delay was the absence of any complete system of representative local government throughout the country. Without this, educational statesmen had no local administrative foundation upon which to build. Thus voluntary effort, necessary and beneficial as it was, had time to harden into vested interests with which the State could not easily contend, and conflicts of opinion upon religious questions,

combined with the more hidden influences of class separation, gained undue power in determining not only the course of the educational controversy, but in affecting the action of the State itself. The weakest points in Forster's own bill were due to the lack of a sufficiency of representative institutions for local government in England and Wales. But his act carried three great principles into effect. It established a compulsory local rate for education where deficiencies in school supply were not met by voluntary effort. It set up a representative local education authority in all districts where public opinion demanded it, or where the failure of voluntary effort rendered it necessary. And it introduced, though at the option of the new local authorities, the principle of compulsory attendance at school. An enduring national system, however, was not created by this bill. But the foundations of a national system were laid, and the machinery of a public system was introduced.

The Act declared that there should "be provided for every school district a sufficient amount of accommodation in public elementary schools available for all the children resident in the district, for whose elementary education efficient or suitable provision is not otherwise made." When there was insufficient accommodation, the act prescribed the manner in which it should be supplied. An elementary school was defined as "a school or department of a school at which elementary education is the principal part of the education there given, and not including any school or department of a school at which the ordinary payments in respect of instruction for each scholar exceed nine pence a week." All public elementary schools were required to be open to government inspection and to conform with the regulations of the Education Department as laid down in the annual code. Any religious teaching or religious observance in the school was required to be given at the beginning or end of a school meeting, in order that, under the conscience clause, any scholar might, at his parents' request be withdrawn from it (sec. 7, 1-23). After due inquiry, the Education Department was to publish a notice of the public school accommodation necessary in each district in England and Wales. If voluntary effort could not supply this accommodation within a reasonable time, or if existing voluntary schools were not likely to be maintained, or if the electors applied for a school board, the Department might order the formation of a school board in every district (a borough or a parish or a combination of these) to be elected triennially by the cumulative vote, in a borough by the burgesses and in a parish by the ratepayers. Women, if independent ratepayers, were entitled to vote equally with men, and any candidate, male or female, resident or nonresident, was eligible for election. Any school board failing in its duties could be declared in default by

the Education Department, which had power to appoint a school board to act in its place. The duty of the school board was to maintain and keep efficient every school provided by them, and to provide such additional accommodation as the members thought necessary. The local rating authority (the council in a borough, the overseers in parishes) were required at the request of the school board to pay the money needed for the purpose by the school board over and above the sums which the latter received from the parliamentary grant, from loans, and from pupils' fees. Any school board might, with the consent of the Education Department, make by-laws requiring the attendance at school of all children between the ages of five and thirteen. In the districts in which there was no school board, no provision for compulsory education existed till 1876. Board schools and voluntary schools received the Parliamentary grant on equal terms, but only the board schools might be aided out of rates. The difference in the case of voluntary schools (as well as the cost of buildings) had to be met out of voluntary subscriptions. (In this connection it may be mentioned that 1500 new buildings were obtained for voluntary schools within the year, for by the act before any district could be forced to establish a board school, six months were to be allowed for this deficiency of accommodation to be made up by private effort.)

The amount of the government grant in each case was determined by compliance with specified conditions as to buildings and teaching staff and "the results" of the teaching of elementary branches as reported by government inspectors. It was further proportioned to the amount raised from local sources. These comprised, for voluntary schools, income from subscriptions, endowments, and fees; for board schools, local taxes and fees. The grant, which reached in 1870 the sum of £562,000 (\$2,810,000), it was anticipated, would eventually furnish 50 per cent of the school income. This proportion, however, was soon exceeded. The grant was strictly limited to schools "public" and "elementary." As defined in the law, a public school was one fulfilling the legal provisions in regard to religious instruction and the code requirements, and open to government inspection; an elementary school was one in which the main part of the education given was elementary and in which the ordinary fee for each pupil did not exceed ninepence a week. School boards were authorized to contribute to the establishment of industrial schools for neglected and abandoned children, and, with the consent of the Education Department, to establish such schools themselves.

For three decades the dual system of elementary schools was developed on the basis of the act of 1870 by successive enactments, of which the principal were as follows.

**Education Acts (1870-1902).** — *Compulsory School Attendance.* — By an act of 1876 the au-

thority given to school boards to make compulsory by-laws with penalties for violation was extended to school attendance committees in districts having no school board; it was provided that the annual grant to a school might exceed the local income, but limited the excess to 17s. 6d. per capita of average attendance; employment of children under fourteen years of age was restricted. In 1880 an act requiring school boards and school attendance committees to make compulsory by-laws with adequate means of enforcement was passed.

*Free Tuition.* — The act of 1891 provided for an extra grant in lieu of fees at the rate of 10s. per capita of average attendance for all schools remitting fees.

*Age of Exemption from School Attendance.* — The act of 1893 made eleven years the minimum age for exemption from school attendance and required an examination in a standard not lower than the fourth for every child seeking exemption from school attendance. The minimum age for exemption from school attendance was raised by an act of 1899 from eleven to twelve years, with special provision for children employed in agriculture.

*Schools for Defectives.* — By laws of 1893 and 1899 school boards were authorized to make special provision for the elementary instruction of blind children, of deaf and dumb children, and of defective and epileptic children.

*Special Legislation.* — The first radical departure from the principles of the original measure was made by the act of 1897, providing a special grant for the benefit of "voluntary" schools at the rate of 5s. per capita of average attendance, and repealing the 17s.6d. limit; also authorizing the federation of voluntary schools and the allotment of the grant at the discretion of the governing bodies of the federations.

*Superannuation Law of 1898.* — This law provides for the retirement of teachers for age (sixty-five years) or disability with an annual allowance. The allowance is made up partly by an annuity purchased by small sums — £3 for a man and £2 for a woman — deducted annually from each teacher's salary, and partly by a state pension calculated according to the years of actual service performed by the teacher. (See PENSIONS, TEACHERS'.)

The laws above cited pertain solely to the province of elementary education; but meanwhile forces within the system and pressure from without had made it impossible to maintain the work any longer separate from all other scholastic agencies. Government recognition of this fact was indicated by the adoption of two measures which completely changed the public administration of education, broke up the isolation of the elementary system, and provided for its coördination with other departments.

**New Administrative Authorities.** — *The Central Education Authority.* — By an act of 1899

a Central Board of Education was created, and to it were transferred the educational functions hitherto performed by the following bodies: The Committee of Council on Education, one division of which administered the grant for elementary schools and another division the grant for science and art schools; the Charity Commissioners, as related to the reorganization of educational trusts and endowments; and the Board of Agriculture. The law did not limit the duties of the new board to elementary education; it provided for "a consultative committee to be constituted by an order in council, consisting of persons qualified to represent the views of universities and other bodies interested in education for the purpose of framing, with the approval of the Board of Education, regulations for a register of teachers" and of "advising the Board of Education on any matter referred to them by the Board." The law also authorized the Board "to inspect any school supplying secondary education and desiring to be inspected."

*Local Authorities.* — In accordance with the act of 1870, voluntary schools were under the exclusive control of private managers; elected school boards had control of the public elementary schools, and through their right to claim rates commanded almost unlimited resources. By the Education Act of 1902, the school boards were abolished and the local control of schools passed to the civil councils of counties and county boroughs. By this act, also, voluntary schools were admitted to share in the local taxes, but without local control. Thus was accomplished not only a complete change in school administration, but a radical departure from long-cherished principles.

*The Annual Codes.* — Down to the year 1902 legislation tended to the one purpose of bringing every child in the kingdom under instruction. Meanwhile the government made itself felt also in the inner workings of the schools. The service of inspection was based, however, upon the right of the State to guard its appropriations instead of its inherent right to regulate the education of future citizens. Consequently the annual codes or regulations, issued by the Education Department with the sanction of Parliament, simply set forth the minimum conditions upon which a school may share in the grant for the year. These conditions, though modified in detail from time to time, have remained unchanged in the essentials included, namely school buildings and equipments, the number and qualifications of teachers, the length of the school session, the attendance of pupils, and the proofs of efficient instruction. Distinct provisions in all these respects are made for the different classes of schools included in the elementary system. These are infant schools (originally for children under seven years of age), schools for older pupils (which comprised at first six standards or grades, subsequently increased to seven),

evening schools (at present included under higher education), and training colleges for teachers.

By the code of 1871, the first issued after the Forster law was passed, a school on the inspection list, above the infant grade, received 6s. per pupil in average attendance, 4s. for every pass in each of the three elementary studies, or a total of 12s. per pupil on the results basis, which sum might be augmented by a grant of 3s. for every pass in specific subjects, but no pupil could present more than two subjects of this class. To be recognized for the grant a school must have met not less than 400 times during the year, and pupils presented for examination must have attended not less than 250 times (150 in the case of half-timers) for a minimum daily session of two hours. It was required that the head teacher should be certificated, and that the staff should bear a certain proportion to the number of pupils. The total grant for an individual school was originally restricted to the amount derived from local sources. In 1876 this requirement was replaced by the condition that the total grant to a school should not exceed 17s. 6d. per capita of average attendance unless the excess was met by an equal sum from local sources. The first important change in the requirements for participation in the annual grant was made by the code of 1882 (Mundella Code), which introduced a merit grant to be awarded at the rate of 1s. to 3s. per capita on the basis of average attendance. The code of 1895 substituted for the annual formal examinations two annual visits by the inspector, to be made without notice, and recognized average attendance as the basis for nearly the whole grant; this arrangement ended the results system, consolidated the grants, and gave greater freedom to teachers.

The codes have been equally explicit as to the grant requirements for infant and evening schools, but the particulars cited illustrate sufficiently the economic principles upon which the annual grant has been distributed. The excessive regard for the formal side of school processes, fostered by this principle, has had the effect of insuring a definite program for every elementary school of England, and very exact information as to the state of school attendance throughout the country. Meanwhile other influences have been working toward the adoption of sounder educational principles.

*Distinctive Features.* — The English system of elementary education was distinguished from the first by the provisions respecting religious instruction, the attendance of half-timers, and the training of teachers. These features still persist, but they have been greatly modified by recent events.

*Religious Instruction.* — Before 1870 no school was subsidized unless connected with the Church of England, the Roman Catholic

Church, or the Wesleyan Church, all of which required the Church doctrines to be taught, while the British and Foreign School Society required the Bible to be read, etc. The state inspectors, with the consent of the managers, were free to examine the religious teaching, and the State paid grants in regard to it. The act of 1870, on the contrary, expressly limited inspection and grants to secular subjects, but it did not forbid religious teaching to be given, if the managers of the school decided to provide it. The central government was to be secular or neutral; the local managers of each school might decide whether any, and, if so, what, religious teaching should be given in their school, subject to restrictions which would make every public elementary school "suitable" for all denominations.

The safeguards provided by the act of 1870 have already been explained. In practice the conscience clause providing for withdrawal from the religious instruction in voluntary schools has proved of little value. As regards board (now council) schools, a few local authorities forbid the teachers to mention religious subjects at all, some provide a simple prayer and hymn, others have Bible reading with or without comment, and a few give place to theological dogma. But whatever the authorities do in regard to this delicate point, they do it on their own responsibility, on the initiative and under the direction of their constituents. The State neither directs, nor controls, nor supervises this teaching.

*Exemption from School Attendance.* — Total and partial exemptions and the system of half-timers have grown out of the relation of the education acts to the factory acts. The factory act of 1802 first made education compulsory in England for any class of children of private individuals living in their own homes. The act forbade the employment of any child between nine and thirteen years of age, unless provided with a certificate showing that he had attended school two hours on six days in each preceding week. By subsequent acts the age limits were made ten to thirteen, and the prohibitions as to employment extended to nontextile factories and in a less stringent form to workshops. At present the factory acts and the education acts agree as far as regards school hours. Both prohibit the employment of a child under twelve years of age (apart from agriculture); neither set of statutes places any restriction (except those relating to "young persons") after the age of fourteen.

It should be noted that the education acts relate simply to school hours, while the factory acts either limit the hours strictly or prohibit work in a factory altogether; a child under age may not be employed there at any hour of the day; a half-timer may only work so many hours or so many days a week. At the age of twelve, and until they are thirteen, children under the factory acts can only be

employed half time; in the case of most by-laws made under the education acts they can qualify for total exemption on reaching twelve. (See CHILD LABOR.) If the by-laws contain a special provision to this effect, children may be employed in agriculture at the age of eleven, provided that they attend school 250 times a year up to the age of thirteen.

According to the official regulations, the term "half-time scholar" means a scholar certified by the local authority to be employed in conformity with the by-laws, or, if not subject to the by-laws, in conformity with the elementary education act, 1876, or any other act regulating the education of children employed in labor, and in either case recognized by the department as a half-time scholar.

"An attendance" means attendance at secular instruction (*a*) during one hour and a half in the case of a scholar in a school or class for infants; (*b*) during two hours in the case of a scholar in a school or class for older children; and during one hour and twenty minutes in the case of a half-time scholar.

**Training of Teachers.** — This topic will be treated in a separate article. See TEACHERS, TRAINING OF.

**Growth of the System (1873-1902).** — The growth and magnitude of this system during the three decades under the law of 1870 are shown by the following tables, which bring into comparative view the enrollment of pupils and the annual expenditure for the schools at the beginning of each of the periods included. In 1873, the first date selected, the law of 1870 was in full operation; in 1883 the compulsory principle had become well established; and by 1893 the "fee grant" provided by the law of 1891 had brought the great body of the schools to a free basis, more than four fifths of the schools having at that date remitted fees, and 4,236,867 pupils, above 82 per cent of the total number, having the benefit of free tuition. In 1903, when the education law of 1902 was just coming into operation, the proportion of free schools had risen to 93 per cent.

From Table I it will be seen that throughout the period covered the elementary education of the masses in England was controlled practically by the Established Church and the elected school boards. In the last decade included in the table (1893-1903) the board schools outstripped the church schools, even in respect to number of pupils. In 1893 they enrolled 41 per cent of the pupils, as against 44 per cent in the church schools; in 1903 the relations were reversed, board schools had run up to 49 per cent of the total enrollment, while church schools had fallen to 39 per cent. The British and Wesleyan schools were rapidly becoming a negligible factor in the problem, as they readily passed over to public control. The Roman Catholic schools, on the contrary, increased; but they represented a very small

proportion of the total school provision, and they reached a particular class of the poor in crowded centers.

The government grant for schools, excluding grants for building and other permanent works, had reached in 1902 the princely sum of £8,000,000 (\$40,000,000). The Church of England schools derived from this source 77 per cent of their income; in the different classes of voluntary schools the proportion ranged from 72 to 80 per cent, the remainder being made up from endowments, subscriptions, and fees. In the board schools, which absorbed 44 per cent of the grant, the income from this source was only 50 per cent of their entire income. The other 50 per cent, excepting a trifling amount, was derived from the rates.

**Education Act of 1902.** — This act of 1902 was the outcome of a political campaign which gave a sweeping victory to the Conservatives; but the problem with which it dealt had arisen from collisions within the system and pressure from without. The situation hinged upon a single fact, the phenomenal progress of the school boards; they had set a pace which the voluntary schools could not maintain; and by upward expansion their schools had come into rivalry with the older secondary schools.

*The Strain of Voluntary Schools.* — In 1896 the school boards were spending an average of \$13 for the instruction of a pupil; voluntary schools spent \$9, a difference of \$4 per pupil. In the cities, the excess of the former ran up to \$7 and \$9 per capita. It was the difference between the steady resources of a public tax and the uncertain action of private benevolence, and was almost entirely represented by a lower payment of the teaching staff. At that time the school boards comprised 68 per cent of the population, concentrated chiefly in cities and towns. Besides the London board, dealing with a population of four and one quarter million, there were 170 school boards in county and municipal boroughs, comprising nine and one quarter million inhabitants. In this number were included Leeds, population (423,899), Liverpool (634,212), Manchester (543,902), Nottingham (239,381), Sheffield (361,169), West Ham (300,241). The school board system was admirably adapted to these great industrial communities, and could count upon their support. At the same time there were about 11,000 parishes without school boards, and of this number 8000 had only Church of England schools. It was, however, generally admitted that the rural parish area was too small for an efficient school board.

The obvious evils of this inequality were aggravated by the very natural antagonism of the Church to the extension of civil control in a province which, at a time not far remote, was exclusively its own. With the return of the Conservative party to power in 1895, this antagonism reached an acute stage, and the education problem assumed from that time the

aspect of a partisan conflict. The Gorst Bill of 1896 was an unsuccessful effort to improve the situation. The following year a special aid grant for voluntary schools at the rate of 5s. per capita of average attendance was allowed. But this amount was entirely inadequate, and the action simply increased the general discontent.

*The Higher Grade Board Schools.* — The entrance of the board school into the province of secondary education introduced a new factor into a most intricate problem. This class of schools had arisen in response to demands created, in part, by the work of elementary schools, and, in part, by changing industrial conditions. They were confined, at least in their organized form, to the large cities, and were supported partly by local tax and partly by grants from the science and art department. They not only came into rivalry with secondary schools of the classical type, endowed, grammar, and private schools, but also with classes and schemes of technical education maintained by the county councils. The purpose of the government to interfere with the higher grade work of the school boards was foreshadowed by the withdrawal from elementary schools (1900) of the grants allowed by the Science and Art Department; the Cockerton judgment (*q.v.*) to the effect that school boards could not apply the income from local taxes for instruction in subjects other than elementary, and by a minute of the Board of Education (Apr. 6, 1900) fixing fifteen years as the upper age limit for pupils in higher elementary schools.

The difficulties of the situation were emphasized by the changes that had taken place in local government since 1870. City administration had been simplified by the Municipal Corporations Act of 1882; later, by the Local Government Act of 1899, the whole of England and Wales had been mapped out into sixty administrative counties and sixty-one county boroughs, having each more than 50,000 inhabitants, making, with the county of London (Greater London), 122 new administrative areas. The governing body in each area is a council formed, like the municipal councils, by popular election. But these measures, which simplified local administration as a whole, further complicated that of the schools. The councils had become education authorities through the control of the surplus liquor duties (Customs and Excise Act, 1890), which were generally used for the promotion of technical education. For the same purpose the councils were authorized to levy a tax (not exceeding a penny in the pound). Hence in the cities and towns there was friction and waste of resources between school boards and the technical education committees of the councils. Everywhere reform was demanded, larger areas for the administration of rural schools, a paramount authority for cities and towns.

The act of 1902 has therefore a double aspect: it was necessary on account of election pledges made by the Conservative party to their clerical adherents; at the same time it was intended to eliminate serious evils by equalizing and unifying the educational provision of the country. The latter aspect was the one presented by Mr. Balfour in submitting the measure to the House. "Its purpose," he said, was "to fulfill the pledge given in the King's speech that a bill should be introduced, dealing not with secondary education or with primary education in their isolation, but with both in one measure and with a view to their better coördination."

To this end, the bill swept out of existence the school boards, and transferred their functions to the county and borough councils. The single authority ideal was at once dissipated by the opposition of the great cities and the clamor of large urban districts. As a consequence boroughs having more than 20,000 inhabitants and urban districts having more than 10,000 were given independent control of their schools. The fear that the higher grade schools would be sacrificed was allayed by the duty imposed upon the councils to supply education other than elementary (Act 1902, Part II). In this connection, a concession was also made to the smaller cities and to urban areas by giving their councils "concurrent powers with the county councils in respect to the expenditure for higher grade schools" (Part II, clause 3). Finally, in view of the fact that the councils were already overtaxed, it was provided that they should delegate their powers under the law — excepting only the power of raising rates or borrowing money — to education committees (Part IV, sec. 17), while both councils and committees were relieved of the oversight of individual schools through the provision of school managers (Part III, sec. 6).

Thus to the councils designated as education authorities in the first clause of the law (in all, 129) were added 201 city councils, 853 authorities for "higher" education, and an indefinite number of education committees and school managers. The authority of the councils was not limited to the schools established by them, but extended equally to voluntary schools. By the original provisions of the bill the conduct of the latter was left wholly to their private managers; but the proposal to place denominational schools upon the rates without any degree of public control raised such a storm of opposition from both Conservatives and Liberals, that a slight but significant modification was made by which the local education authorities were allowed to appoint two out of six managers of voluntary schools; at the last moment the Kenyon-Slaney clause was carried, which placed the religious instruction under the control of these managers (Part III, secs. 6, 2; 7, 6). The managers of voluntary schools are further required in particular to carry out

any direction of the local education authorities in respect to secular instruction, provide the schoolhouses free of charge, keep the buildings in good repair, and make such improvements in them as may reasonably be called for.

The constitution of the education committees was carefully provided for, and it was expressly ordered that women should be appointed upon them. This was a significant admission of the great service women had rendered as members of the school boards, although it failed to give them place in the really authoritative bodies, *i.e.* the councils, which was urged by progressive men and women all over the country. Henceforth the former board schools are to be known as public elementary schools provided by the local education authority (or, briefly, "provided" or council schools); the former voluntary schools, as non-provided.

It should be noted further that whereas the act of 1870 placed no restrictions upon the upward development of elementary schools, the present act is explicit on this point, and gives the first definition of elementary education in English law. It provides that: "In this act and in the elementary education acts the expression 'elementary school' shall not include any school carried on as an evening school under the regulations of the board of education. The power to provide instruction under the elementary education acts, 1870 to 1900, shall, except where those acts expressly provide to the contrary, be limited to the provision in a public elementary school of instruction given under the regulations of the board of education to scholars who, at the close of the school year, will not be more than sixteen years of age; *Provided*, That the local education authority may, with the consent of the board of education, extend those limits in the case of any such school if no suitable higher education is available within a reasonable distance of the school. The power to supply or aid the supply of education other than elementary includes a power to train teachers, and to supply or aid the supply of any education, except where that education is given at a public elementary school" (Part IV, clause 22).

The act of 1902 went into effect Mar. 26, 1903, and in August of the same year a similar act was passed for London, which had not been included in the general measure. In the new era thus opened, elementary education, while retaining its separate aims, has become part of a more comprehensive system. This change was foreshadowed by the act of 1899, creating the Board of Education; and would have been impossible, if the local school boards, the "*ad hoc* bodies," to quote a popular term, had not been replaced by the councils which are charged with the whole range of local affairs. The unity of local administration has, however, introduced new elements of discord. The opposition to the act of 1902, roused by the overthrow of the urban school boards, by the

restrictions upon municipal authorities, and the appropriation of local taxes to sectarian schools, has never ceased. "Passive resistance," the refusal of the Welsh councils to enforce the act, the coercive measures of the government, have all become matters of history. It is admitted that the present stage of the system is temporary; nevertheless, it is a stage in a progressive movement determined by three forces: the Board of Education, the local authorities, and the advancing ideal of public education. Although simultaneous in their action, these agencies may, for convenience, be separately considered; and, first, with regard to elementary education alone.

*Board of Education.*—The directive and unifying influence of the central board is accomplished by the service of inspection, by the annual codes, by reports of special inquiries, and by instructions issued from time to time on subjects of timely interest or pressing importance. The whole scheme of elementary education has been rearranged, the annual grants are now paid on a system which distinguishes between pupils on an age basis, the age of five years, the lower limit of compulsory education being taken as the line of division between infant schools or departments and those for older scholars.

Higher elementary schools must be organized to give a three-year course of instruction approved by the Board of Education, and must be specially equipped for the course. Admission to schools of this grade is limited to pupils who are over twelve years of age at the date of admission, and have been for at least two years under instruction in a public elementary school. The number of pupils habitually taught in a class must not exceed forty, and there must be a teacher for every class.

The most important measures adopted by the Board of Education for the improvement of elementary schools relate to the teaching staff and the school premises. The new requirements have reduced the "staff value," that is, the maximum number of scholars to one teacher of a specified class, by an average of about 20 per cent. Each school staff must include at least one certificated teacher for every eighty pupils in average attendance, and no class should exceed sixty registered pupils. As regards school premises, measures have been taken to insure that in all new schools there shall be not less than ten square feet of floor space for each older child, and nine square feet for each infant. At the same time the board inspectors, with the coöperation of the local authorities, have made a comprehensive review of all cases in which school premises are defective or unsuitable, and with this knowledge the necessary changes can be insisted upon. In every case, the plans for new school buildings, and for the alteration or enlargement of old buildings must be approved

by the department in order that the schools should be recognized for grants.

*Grants.*—While the tendency is to raise the standard in respect to all the conditions required for the government grant, the basis of allotment has been simplified. The grants for elementary schools are at present as follows: *The annual grant*, allowed at the rate of 13s. 4d. for each unit of average attendance of children under five years of age; at the rate of 21s. 4d. for each unit above that age. An *aid grant*, which takes the place of the special grant for voluntary schools provided by the act of 1897. This aid grant is at the rate of 4s. per pupil, with an additional 3d. in areas where the product of the school tax is less than a specified minimum. *The fee grant* (law of 1891); *special grants* for areas having small populations. *Grants for special subjects* are allowed upon certain conditions pertaining to the age of pupils, the number in attendance, and the equipment of the school for effective instruction. The subjects classed under this head are: cookery, laundry work, housewifery, combined domestic subjects, dairy work, handicraft, light woodwork, and gardening.

Schools organized as higher elementary schools in addition to the aid grant and the fee grant have the following:—

FOR EACH UNIT OF AVERAGE ATTENDANCE OF SCHOLARS IN THE		AMOUNT
First-year course . . . . .		30s.
Second-year course . . . . .		45s.
Third-year course . . . . .		60s.
Fourth-year course (when sanctioned) . . . . .		60s.

Evening schools, which had been well organized under the great urban school boards, are now included under secondary education.

*Recent Changes in the Board.*—To meet the enlarged ideals of popular education, the central board has made important changes in its own organization. Among these should be mentioned first the establishment of a medical department "to advise and assist the board in carrying out their statutory duties in this regard; in giving direction as to the frequency and method of medical inspection (*q.v.*), and in considering and sanctioning such arrangements as may be proposed under the act by the individual authorities." Second, the consultative committee has been increased from eighteen to twenty-one members, care having been taken to fill the new places and the vacancies caused by resignations with persons representing various aspects of education that have hitherto had no direct representation in the committee.

In accordance also with the determined purpose of the Welsh councils and people, as embodied in the last bill of 1906 (Part III), the board established in the following year a special department for the administration of education in Wales, under the control of a permanent

secretary and a chief department inspector, each responsible directly to the president of the board. This arrangement applies also to Monmouthshire, England, which was included in the previous Intermediate Education Act for Wales. In consequence of this distinct administration, the Welsh schools are now treated on an independent basis.

*Local Authorities.*—The difficulty in the way of focusing attention upon the details of the educational work arises from the number of local authorities upon which the execution of the education act depends, and which, within the limits of the law, have large independence. These authorities number at present 328, including 62 county councils, 74 county boroughs, 137 autonomous municipal boroughs, 54 urban districts, and the Isles of Scilly. The transfer of authority from the former school boards to the county and borough councils, and the formation of education committees, as required by the act of 1902, were accomplished with very little delay or friction, and the committees generally entered upon their duties with great energy. The chief advantage of the change, elementary schools alone considered, appears in rural districts. The power of grouping schools under one body of managers, accorded to the local authorities, has resulted in several counties in converting isolated schools into units of a county system. Further, when regarded as parts of the county system, different classes of schools, provided, non-provided, elementary, and higher elementary, are better coordinated, and can more readily be adjusted to local needs. Experience has shown, however, that while the county is a desirable area for some purposes, local interest in school matters has declined by the sacrifice of direct popular election of the controlling authorities.

The prevailing opinion on this subject was voiced in a resolution unanimously adopted by the National Education Association (England) as follows: "That in view of the acknowledged need to secure greater local interest and real popular control in educational affairs we consider that reforms in the system of local administration are urgently needed, especially in the direction of securing the direct popular election of local authorities having only educational duties to perform." It may be recalled here that the defeated bill of 1906 provided for reform in this respect by a clause which received the assent of both houses.

The distribution of pupils under the different classes of local authorities for the last year reported was as follows: Counties, 2,439,907; London, 748,262; county boroughs, 1,820,240; boroughs of 20,000 or more inhabitants and urban districts of 10,000 or more, 1,067,559. Thus it appears that of the total enrollment, viz. 6,075,968, there were 3,636,061 pupils, or 59 per cent, in urban schools.

Prior to the passage of the act of 1902, areas having no school board did not levy a rate for

education (school tax). By that act the rate is universalized. It is estimated that of the entire ratable value of England and Wales, £186,500,000, fully sixty millions were thus brought, for the first time, under compulsory contribution toward elementary education. The local rate ranges from a minimum of 3*d.* in the pound to a shilling and upwards. The act of 1902 restored, also, the principle of proportioning the grant for schools to the amount provided locally.

The independence of local authorities is illustrated by the recent action of the London County Council in withdrawing the twenty-two schools recognized as higher elementary from the grant list of that grade, in order that they might be perfectly free to develop these schools according to their local demands untrammelled by official rules. Experiments in vocational education have been begun in several of these schools since this course was adopted.

The number of local authorities seeking the sanction of the Board of Education in 1909 for providing meals to school children from the rates was 56. The number of authorities reporting medical inspection officers was 307 out of the total of 328. These areas included for England 45 counties, 66 county boroughs, 132 municipal boroughs, 42 urban districts; for Wales, 6 counties, 4 county boroughs, 4 municipal boroughs, and 8 urban districts.

**The Advancing Ideal of Public Education.**—The work of the local education authorities has been vastly increased by the extended scope of the system. The scholastic extensions provided for by the act of 1902 will be considered presently; more intimately related to the elementary schools is the social welfare work which centers in them or seeks their cooperation. Among many causes of the latter development, not the least is the thorough knowledge of the child population acquired originally by the school boards and necessarily maintained by the present authorities. Even the system of payment-upon-results had this to commend it, that it called attention to the evils of under-feeding, home toil, confusion, and misery, which often made it impossible for a child to meet any requirement. Varying forms of assistance were started under these conditions, for which legal provision has recently been made, placing a large degree of responsibility upon the education authorities.

By the Education (Provision of Meals) Act of 1906, the councils were authorized to incur expenses and adopt plans for supplying meals to children attending public elementary schools. (See FOOD AND FEEDING OF SCHOOL CHILDREN.)

The Administrative Provisions Act of 1907 authorizes local councils to maintain "for children attending a public elementary school, vacation schools, vacation classes, play centers, or other means of recreation during their holidays or at such other times as the local educa-

tion authority may prescribe, in the schoolhouse or in some other suitable place in the vicinity, so far as the local education authority, in the case of a schoolhouse or place not belonging to them, can obtain for the purpose the use of the schoolhouse or place. The law also makes it the duty of the local authorities 'to provide for the medical inspection of children immediately before or at the time of, or as soon as possible after their admission to a public elementary school, and on such other occasions as the Board of Education direct,' and 'to make such arrangements as may be sanctioned by the Board of Education for attending to the health and physical condition of the children educated in public elementary schools.'

The Children Act of 1908, though not strictly educational, increased the duties of the local education authorities, especially as regards school attendance and children remanded to an industrial reformatory or to a day industrial school. More and more, also, social welfare work tends to center in the schools. After-care committees and juvenile employment bureaus are in the process of becoming regular adjuncts of the city systems, regulated by law and entailing a vast amount of work and expense. This extension adds greatly to the current expenditures for the schools, but Treasury grants are not increased proportionately, and the burden falls heavily upon the local rates. (See CHILDHOOD, LEGISLATION FOR THE CONSERVATION AND PROTECTION OF.)

The child welfare movement is inseparable from the greatest educational problem of the present time, namely, the problem of continuation education, or the means of prolonging the education of the industrial classes beyond the ordinary school period, and of rendering this continued training vitally effective. The importance of this subject has been recognized on the part of the Board of Education by its reference to the consultative committee, who made an exhaustive investigation of the question in all its bearings. The burden of the committee's report is the incompleteness of elementary education, and the "tragic waste" of early promise. The waste is attributed largely to the lack of training which prepares, at once, for useful industry and for harmonious relation to organized society. The committee estimated that there were 2,000,000 boys and girls in England and Wales between the ages of fourteen and seventeen, of whom 75 per cent were receiving on week days, at least, no school education, and who were spending the time in illness or in mere makeshift employments. Although convinced that the time has not yet come when compulsory attendance at continuation schools can be enforced throughout the country, the committee were unanimous in the opinion that the extension of the period of formal training is essential for national, as well as for individual, welfare.

See INDUSTRIAL EDUCATION; CONTINUATION SCHOOLS; EVENING SCHOOLS.

The immediate outcome of the investigation is a more intelligent comprehension of the problem, with, here and there, practical attempts at its solution. Most significant of these attempts are the measures taken by great industrial firms to induce their young employees to continue their education. Several instances are reported of firms that allow time for the purpose without loss of wages and with the prospect of advance and larger remuneration by reason of increased competency. (See APPRENTICESHIP AND EDUCATION.) On their part, the municipal councils are encouraging continued attendance at evening schools and at the higher elementary schools by scholarship funds, many of which, in addition to free tuition, give financial aid to the recipient.

The most impressive evidence of the advance in public opinion as to the value of education is afforded by the strong opposition to the continuance of the half-time system. A School Attendance Bill was submitted to the House of Commons in 1908, providing that the minimum age for exemption from school attendance should be thirteen years. The relation of this measure to the general welfare of juvenile workers was clearly shown by its author, Lord Stanley of Alderley, in his speech moving the second reading. He pointed out that while the Education Act of 1902 empowered local authorities to make by-laws giving partial exemption from school attendance, from May to October, to children employed in agriculture, that provision had not been taken advantage of at all. Nearly all the half-time employment in the country of children over twelve years of age, according to Lord Stanley, "is in the textile districts," and outside those districts "there is practically no half-time." Even where it exists, the figures support the view "that it is not a necessary condition of industry, even in the textile trades." The bill was not carried to second reading, but an interdepartmental committee was appointed to inquire into and report upon the whole subject of exemption from school attendance, the conditions of child labor, and the practical effects of legislation restricting the employment of children. In connection with this bill, the action of the United Textile Workers' Association is significant. The leaders of this association assembled in conference, by a vote of 186 to 27, approved the raising of the age of half-time labor from twelve to thirteen years. This is a striking evidence of the change that has taken place in the minds of this class of workers. For thirty years they have steadily opposed the steps by which the age for half-time labor has been raised from eight to twelve years. The committee above referred to agreed in an unqualified condemnation of the half-time system, and recommended its speedy abolishment. The question is once more before Parliament, and a

bill was presented in March, 1911, by Mr. Runciman, tending to raise the age of exemption from school attendance, and adding to it compulsory attendance at a continuation school. (See PART-TIME SCHOOL ATTENDANCE.)

**Classification and Scope of Elementary Schools.**—The ordinary elementary schools are classified as infant schools (for children under eight years of age, normal ages five to eight) and schools for older scholars (*i.e.* ages eight to fifteen). Prior to 1902 the annual codes presented the general program for each class of schools, and also schedules showing the part of the program to be covered by each "standard" or grade. In order to allow greater freedom to individual schools in this respect, the standard schedules have been omitted from the recent codes, but the instruction in every school must follow a definite syllabus which has official sanction. The codes not only comprise the general program of studies, but also give suggestive instructions as to methods and aims; from time to time, model programs are also issued by the Board, and even elaborate manuals pertaining to individual subjects.

As regards infant schools, the free development of body and mind and the formation of habits of obedience and attention are the ends to be attained. For the younger "infants" there are games, simple manual exercises, stories, and familiar talks with the teacher, and for the older "infants" (five to eight) short lessons, in which they are trained "to listen carefully, to speak clearly, to recite easy pieces, to reproduce simple stories and narratives, to cultivate their powers of observation, to do simple things with their hands, to begin to draw, to begin to read and write, to acquire an elementary knowledge of number, to practice suitable songs, and to sing simple musical intervals." Instruction in sewing and knitting may also be given, care being taken to avoid fine work and injury to the eyesight.

The program of the schools for older scholars comprises: English language, writing, arithmetic, drawing, including modeling, observation lessons and nature study, geography, history, singing, hygiene and physical training, and for girls domestic subjects. Instruction in morals is required, but may either be incidental and occasional, as opportunity arises in the ordinary routine of lessons, or may be given systematically and by a course of graded lessons. It is not expected that every one of these subjects should be taken by every class, but a school must make provision for them all. The three elementary studies form the nucleus of the work of each class, and are the only subjects required for the examination for certificates which exempt children from compulsory school attendance.

The government inspectors are required to examine for a certificate of proficiency any child over twelve years, or any child over eleven years of age who is to be employed in agriculture under any by-law of the school attendance acts,

whether he be a scholar in the school or not, if the child's parent or guardian or the authority apply to have him examined for such a certificate. As a rule children are not presented in a lower standard than the fourth, and hence the examination schedule for the fourth and higher standards, as given below, may be taken as an index to the class programs in the standard subjects, around which the remaining subjects are arranged as suits the conditions of the respective schools.

STANDARDS OF EXAMINATION IN THE ELEMENTARY SUBJECTS

	STANDARD IV (AGE 11 YEARS)	STANDARD V (AGE 12 YEARS)	STANDARD VII (AGE 14 YEARS)
Reading . .	To read a passage from a reading book or history of England.	To read a passage from some standard or a reading book, or a history of England.	To read a passage from Shakespeare or Milton, or from some other standard author, or from a history of England.
Writing . .	Eight lines of poetry or prose, slowly read once, and then dictated. Copy books to be shown.	Writing from memory the substance of a short story read out twice; spelling, handwriting, and correct expression to be considered. Copy books to be shown.	A theme or letter. Composition, spelling, and handwriting to be considered. Notebooks and exercise books to be shown.
Arithmetic (Scheme A.) <sup>1</sup>	Compound rules (money) and reduction of common weights and measures.  In the Table of Length only yards, feet, and inches will be required in this and the Fifth Standard.	Practice, bills of parcels, and single rule of three by the method of unity.  Addition and subtraction of proper fractions with denominators not exceeding 12.  Common weights and measures.	Averages, percentages, and stocks.

The examination in arithmetic is conducted in accordance with a prescribed syllabus. Children who are presented in the seventh standard are examined in the whole of the syllabus, which extends through percentage and interest. Children presented in standards below the seventh take proportional parts of the syllabus. In the case of children as low as the third standard, the examination includes only the four elementary processes and examples in the use of weights and measures.

*Special Subjects.*—In addition to the obligatory subjects, extra grants are allowed for special subjects, which must be taught according to an approved syllabus, in premises properly equipped for the purpose, by teachers of ap-

<sup>1</sup> An alternative scheme B is given for arithmetic, which carries the work in each standard a little further than scheme A. Short exercises in mental arithmetic are given in every standard.

proved competence, and to pupils over eleven years of age. These subjects include cookery, laundry work, housewifery, domestic subjects, dairy work, handicraft, and gardening. (See HOUSEHOLD ARTS.)

**Higher Elementary Schools.**—The higher elementary schools complete the course of instruction available for the majority of English children. To be recognized as *higher elementary*, a school must be necessary; must be organized to give a three-year course of instruction approved by the Board of Education, and as regards teaching staff, buildings, and equipment, must meet the official requirements. The course of instruction is intended to extend that of the ordinary public elementary school, and to provide for training of a vocational character, the latter to be determined by local needs. The general course must include the English language and literature, elementary mathematics, history and geography, drawing and manual work for boys and domestic subjects for girls.

The number of scholars in a higher elementary school should not exceed 350; and admission is limited to scholars who are over twelve years of age and who have been for at least two years under instruction in a public elementary school. Except by special agreement, scholars may not remain in a higher elementary school after completing the third year of the course, or for any portion of a school year at the close of which they will be more than sixteen years of age. The number habitually taught in a class must not exceed forty, and there must be a teacher for every class.

Schools fulfilling the required conditions are entitled to the following grants:—

For each unit of average attendance of scholars in the	Amounts
First Year Course . . . . .	30s.
Second Year Course . . . . .	45s.
Third Year Course . . . . .	60s.
Fourth Year Course (when sanctioned) . . . . .	60s.

The entire enrollment in the different classes of public elementary schools, for the latest year reported (1908-1909) was 6,060,110. Of this number 6.8 per cent were younger infants (*i.e.* below five years of age), 21.6 per cent were from five to seven years of age; 53.5 per cent were seven to twelve years. The number enrolled above twelve years of age was 1,097,842, or 18.1 per cent of the total. The enrollment in higher grade elementary schools complying with the official regulations was only 9720, or less than 1 per cent of the number above twelve years of age. Hence it appears that the development of this class of schools proceeds very slowly. It should be noted that the London County Council has withdrawn its higher elementary schools from the special grant list, and is conducting them under the regulations for ordinary elementary schools. This change, which reduces the number of pupils reported in the higher grade, was taken in order that the council might develop schools of this order

according to local needs, unrestricted by official conditions.

**Relations between Public Elementary Schools and Schools of Higher Order.**—The official regulations declare it to be "an important though subsidiary object of the elementary schools to discover individual children who show promise of exceptional capacity, and to develop their special gifts (so far as this can be done without sacrificing the interests of the majority of the children), so that they may be qualified to pass at the proper age into secondary schools, and be able to derive the maximum of benefit from the education there offered them." The transfer of pupils from elementary to secondary schools should take place not later than the twelfth year of age; but an earlier age is encouraged by a grant paid on transferred pupils between the ages of ten and twelve years, equivalent to the grant allowed for pupils in the public elementary schools. The main grant in secondary schools, however, is paid in respect of pupils between the ages of twelve and eighteen years.

The early age of transfer is advised for both social and educational reasons. The latter may be readily understood by reference to the preparatory schools, a special class of private schools intended to prepare pupils for the endowed public and grammar schools. They number at the present time about 360, with an average enrollment of thirty-seven pupils each, of ages nine and one half to thirteen and one half. The headmasters of these select preparatory schools are generally graduates of Oxford or Cambridge, and former pupils of the endowed public schools, and hence they infuse into their schools the spirit and traditions of the older institutions. The pupils from the ordinary elementary schools have been under totally different influences, and it is difficult to assimilate them to the tone of the secondary school; at the same time they have followed a course of study differing essentially from that of the regular preparatory schools.

For children of ordinary ability who leave the elementary school at twelve or thirteen years of age, evening schools offer opportunity for continued training, and as these schools are classed under the head of higher education, there are two diverging roads leading upward from the elementary school, one to secondary and the other to continuation schools. These relations presuppose a degree of continuity in the elementary and advanced courses of study.

**Secondary Schools.**—The Education Act of 1902 provides that "the local education authority shall consider the educational needs of their area, and take such steps as seem to them desirable, after consultation with the Board of Education, to supply or aid the supply of education other than elementary and to promote the general coördination of all forms of education." (Part II, sec. 2, (1)). This provision brought the whole field of education lying be-

tween the elementary schools and the universities — that is, secondary schools and technical schools — within the province of the local education authorities, either for aid and supervision or as factors in the general scheme of co-ordination. As regards technical schools and classes, the relation had already been established; in respect to secondary schools it was a new departure. Hence, reference must here be made to previous measures leading directly to this result.

The British Schools Inquiry Commission appointed in 1867 classified the secondary schools of England as first grade, or schools which continue the education of scholars up to the age of eighteen years or more; second grade, schools which carry the education up to the sixteenth year of age; third grade, schools for pupils whose education ends at about fourteen years of age. This classification has ever since prevailed, not as a formal scheme, but as an underlying principle corresponding in the main to social conditions.

The first-grade secondary schools lie outside the pale of local direction, although by reason of their relation to the supervisory functions of the Board of Education, they are brought within the recent movement. This exclusive class comprises the famous public schools which were the subject of special investigation by Lord Clarendon's Commission of 1861. They include seven endowed boarding schools, namely: Winchester, founded in 1382; Eton, 1440; Shrewsbury, 1552; Westminster, 1560; Rugby, 1567; Harrow, 1571; and Charterhouse, 1611; and two endowed day schools of a local type, — St. Paul's, 1509, and Merchant Taylors', 1561, both in London. In respect to their patronage and their influence in forming the character of the leading men of the kingdom, these schools are justly regarded as national institutions. (See PUBLIC SCHOOLS.) The report of Lord Clarendon's Commission, issued in 1864, led to the passage of the Public Schools Act of 1868 dealing with the seven boarding schools named above. This act provided for the appointment by the schools of new governing bodies which were to make new statutes and regulations for their respective institutions, subject only to approval by the Privy Council. Apart from the required removal of certain narrowing restrictions, and the assent of the Privy Council to their schemes, the new governing bodies were left with a free hand. At that time these schools had an aggregate annual income of £65,000 (\$325,000), and were attended by nearly 3000 students, the élite youth of the country.

In 1864 the British Schools Inquiry Commission (under Lord Taunton) was appointed to inquire into the condition of the remaining endowed schools, 820 in number, which had been established at different times through the long period of seven centuries. Included in the same inquiry were 122 proprietary schools, or schools maintained by stock companies. Of the

endowed schools 572 were regarded as secondary. They numbered about 40,000 students, and had a net aggregate annual income of £183,066 (\$915,333), with exhibitions of the annual value of £13,897 (\$69,485). Private schools, sometimes termed private adventure schools, were also included in this investigation.

From the report of the British Schools Inquiry Commission it was evident that the country was alarmingly deficient in secondary schools for the middle and laboring classes. There were at least a hundred towns with a population of 5000 or more that had no endowed grammar school. London, whose population at the time was nearly 3,000,000, had only twenty-six endowed schools, with less than 3000 pupils. More than half the population of the city (1,726,989) were destitute of any endowment for secondary education. Not only was the supply of public secondary schools far below the demand, but those that existed were often badly managed, their resources wasted, and their influence meager. In particular the commissioners noted the dearth of day schools. The report of this commission led in 1869 to the passage of the Endowed Schools Act (*q.v.*), which has had important results in respect to the particular schools affected. It embodied, however, only a single one of the recommendations of the Commission, namely, that calling for a central authority to draft new schemes for the administration of the endowments. This duty was intrusted at first to three special commissioners; in 1874 it was transferred to the Charity Commission (constituted under law of 1853), and finally, in 1899, to the newly constituted Board of Education.

For several centuries the expression "national education" applied in England to the discipline and culture of the great public schools, rounded out and completed by Oxford and Cambridge. The endowed grammar schools followed the same classical course, and sent their quota of students to the universities. But a new era was ushered in by the Reform Bill of 1832. The commercial and industrial classes rose to power, and for the changed demands of public life a new order of training and schools, less exclusive and less expensive than the old endowed schools, were required. King's College School, opened in 1829, and University College School, 1833, both in London, were modern in their purposes, and this was still more pronounced in the case of the City of London School, created by Act of Parliament in 1843, upon the basis of a bequest made four centuries earlier (1442).

The movement thus begun spread rapidly to all the populous centers of England. Stock companies were formed in some instances for the maintenance of schools, and in other cases a corporate system was adopted whereby any one could purchase the right, for a certain sum, to send a boy to the school in question, at a reduced rate. Among these proprietary schools, as they are called, several can be named of

scarcely less distinction than the famous nine. Such are: Cheltenham College (1811); Marlborough College, for the sons of clergymen (1843); Clifton College (1862); and Bath College (1876). They imitated the older schools in the principles of their education, and took their headmasters from them. Rugby was especially preferred by the founders of the new schools on account of its reputation, which was then at its height, thanks to the labors of Dr. Arnold (*q.v.*). Their plan of study differed from that of the older schools. Together with the ancient languages, provision was made for mathematics and natural sciences, history and modern languages in such a way that, together with the "classical side," a "modern side" was organized. The former prepared its students for the university, while the latter fitted them for official and commercial careers. As a rule proprietary schools tend to become, in time, either independent endowed schools or simply private schools. A certain amount of uniformity in secondary education, both for boys and girls, was secured by the numerous examining bodies which sprang up in the second half of the nineteenth century. (See EXAMINATIONS.)

A return made to the House of Commons in 1892 showed great progress in the provision for secondary education, as a result of the labors of the previous commissions. The income of educational endowments available for secondary education, exclusive of property of an incalculable value in the form of sites and buildings for schools, was reported as £697,132 (\$3,485,660). Of 1262 distinct endowments, 668 were then being managed under schemes approved by the Charity Commission. Comparison with the earlier conditions showed that many new schools had been endowed or established by other forms of private initiative during the period. This was marked in respect to schools for girls, to which subject the report of the Taunton Commission had devoted a chapter. Within ten years endowments had been furnished for forty-five schools for girls, with provision for fifty to one hundred pupils each. The Girls' Public Day School Company (*q.v.*), organized in 1873, extended its work so rapidly that in 1897 it had thirty-four schools, with 7150 pupils.

**The Board of Education and Secondary Education.** — The authority conferred upon the Board of Education to pass final judgment upon the revised schemes for endowed schools has already been referred to. It remains only to consider additional functions of the Board in respect to "higher education" growing out of the Education Act of 1902. These functions are exercised in practically the same way for all secondary and technical schools below the universities and the great public schools. Regulations are issued setting forth the conditions on which the Parliamentary grants may be obtained, and for schools meeting those conditions a service of inspection and examination is maintained by the Board, by means either of

its own inspectors or of the agencies which it may recognize for the purpose (universities and other organizations).

In regard to technical schools and classes, this is a continuance of the work formerly carried on by the Science and Art Department; but in the case of secondary schools the relation is new, and is effecting radical changes in the spirit and purposes of secondary education in England. Secondary schools are free to accept or reject government aid and inspection, but if they accept, they must comply with the official requirements.

*Conditions Pertaining to Grant-aided Secondary Schools.* — The term "secondary" is applied by the Board to "any day or boarding school which offers to each of its scholars, up to and beyond the age of sixteen, a general education, physical, mental, and moral, given through a complete graded course of instruction of wider scope and more advanced degree than that given in elementary schools." The course of a secondary school is not considered to be complete unless it is planned to carry the scholars to such a point "as they may reasonably be expected to reach at the age of sixteen." It may begin at the age of eight or nine, or even earlier; scholars may pass into it from elementary schools at various ages beyond this, up to twelve or thirteen, and in schools of a high grade which give an education leading directly on to the universities, it may be continued up to the age, even, of eighteen or nineteen. As a rule, the years from twelve or thirteen up to sixteen or seventeen are those to which the official regulations are directed.

It is expressly required that a grant-aided school shall be efficient and shall not compete unduly with a neighboring school; that no religious test or requirement as to religious observances or attendance upon religious exercises shall be imposed upon day scholars; the curriculum and time-table of the school must be approved by the Board of Education; a full account of the income and expenditure of the school must be annually submitted to the Board; the fees charged, the school premises, equipments, and appliances must be satisfactory to the Board; and the school must be open at all times to inspection by the Board. It is further provided that the school shall meet regularly during not less than thirty-six weeks in the course of the school year, and for not less than four hours each school day; that the teaching staff shall be sufficient in number and qualifications; the salaries offered shall not be subject to variation according to the amount of grant received, and the registers must show not less than twenty qualified students above twelve years of age in the approved course of secondary education.

The obligatory subjects of the course are the English language and literature, at least one language other than English, geography, history, mathematics, science, and drawing. A curriculum including two languages other than Eng-

lish, but making no provision for instruction in Latin, will only be approved where the Board are satisfied that the omission of Latin is for the educational advantage of the school. The instruction in science must include practical work by the pupils.

Provision must be made in all the schools for organized games, physical exercises, manual instruction, and singing. Schools for girls must offer practical instruction in domestic subjects, such as needlework, cookery, laundry work, housekeeping, and household hygiene; for girls over fifteen years of age an approved course in a combination of these subjects may be substituted, partially or wholly, for science and for mathematics other than arithmetic.

In all fee-charging schools free places must be offered at the beginning of the school year to pupils entering from public elementary schools under the conditions laid down in the regulations. The number to be offered will ordinarily be 25 per cent of the total number of pupils admitted to the school during the previous year, or, in the case of a new school, at its opening; but this percentage may be reduced or varied by the Board on sufficient grounds in the case of any particular school. (See SCHOLARSHIPS.) The governing body of a grant-aided school, where it is not the local education authority of a committee of the same, must contain a majority of persons representing a popular constituency.

Within the limits of these general conditions, different types of secondary schools are recognized as suited to the different requirements of the scholars, having regard to their place in the social organization, to the means of the parents and the age at which the regular education of the scholars stops, as well as to their probable future occupations and opportunities."

To the secondary schools that meet the specified conditions, annual grants are paid, as follows: For each pupil between ten and twelve years of age, and who, for two years immediately before entering the secondary school, had attended a public elementary school, £2 (\$10).

For each pupil twelve to eighteen years of age, £5 (\$25).

An additional grant at the rate of £1 (\$5) for each pupil twelve to eighteen years of age in a school which provides: (1) for the preliminary education of elementary school teachers as bursars or in a pupil-teacher center forming an integral part of the school; and (2) has offered not less than 25 per cent of free places.

Extra grants are also made to schools receiving French or German assistants under plans arranged with the respective foreign governments. These grants were given in the year 1908-1909 to two schools in respect of one 'assistant' each, in the year 1909-1910 to twenty-two schools in respect of twenty-three 'assistants,' and in the year 1910-1911 they will be payable, if the prescribed conditions are duly fulfilled, to twenty-two schools in respect of twenty-five 'assistants,' three of the schools receiv-

ing both a French and a German 'assistant.'"

Special grants are also offered to schools that adopt methods of exceptional value in the conduct of particular branches of study or in the general management of the school. The experiments that meet the approval of the Board are set forth in detail in a series of educational pamphlets, of which two have already been issued: one relating to *The Teaching of Latin at the Perse School, Cambridge*, and the other to *A School Week in the Country*, an interesting experiment on the part of the girls' department of a secondary school in Bradford. According to the official report, "there is much more disposition in the case of the girls' schools than in schools for boys to favor experiments and give free play to fresh ideas. . . . The Board has increased the staff of women inspectors to assist in the successful and sympathetic handling of this side of their work."

As regards curriculum, the earlier efforts of the Board were directed mainly to scientific subjects, in which the schools were generally weak. At present, literary subjects are being emphasized, and thus the whole scheme of secondary studies is undergoing revision. There is also a noticeable disposition on the part of the Board to substitute intelligent inspection for the excessive strain of stated examinations.

**Local Authorities and Secondary Education.**—The Board of Education has become a unifying force in the entire field over which its authority extends, by virtue of the grants which it disburses, the standards which it maintains, and the model schemes and detailed instructions which it publishes; but the more important purpose of equalizing the educational provision of the country rests with the local education authorities. In this respect their powers are extensive. They may apply the proceeds of the liquor duties allowed them under the act of 1890 to this work, and may levy special taxes for higher schools. As a rule the local authorities have entered with energy upon these duties. In the chief boroughs and in all the larger counties, notably in London, Sheffield, Birmingham, Liverpool, and Manchester, and in the counties of Lancashire and Yorkshire, the whole field has been carefully surveyed under expert direction, and systematic plans formed for the improvement of existing schools and the establishment of new schools. In 1905 there were 122 secondary schools provided by the local authorities, not including Wales. In 1910, out of a total of 841 secondary schools on the grant list, 325 were maintained by the local authorities. These included schools originally provided by the local authorities, and former endowed or proprietary schools which have been transferred to them. The 516 remaining schools have popular representatives upon their governing boards, and are in many cases aided by local grants. Thus by a gradual process the old type of secondary schools is being absorbed, as it were, into the public system.

In addition to the secondary schools on the grant list there were eighty-seven schools recognized as efficient, making, with 109 schools in Wales, a total of 1037 secondary schools under government inspection. They registered 172,244 pupils (boys, 92,743; girls, 79,501). Of this total more than one fourth were on the free basis.

**Coeducation.** — Many rural districts are unable to support separate schools for boys and girls, and consequently adopt coeducation; the policy is spreading also to towns of considerable size. Of the 928 schools in England, recognized as efficient in 1909-1910, there were 150 in which boys and girls were taught together throughout the school, and 23 in which they were taught together in some classes.

In Wales, where the majority of the secondary schools are provided by the local authorities, out of a total of 109 schools on the grant list, 59 were coeducational, 25 were for boys only, and 25 for girls only.

**Specialized Continuation Schools.** — Evening schools are a link between the system of elementary education and specialized schools of science and art. Since the transfer of this entire work to the Board of Education, progress has been made in the organization of the varied forms of evening schools and classes, particularly in the more densely populated boroughs of the north of England, where the effort is supported by the pressing needs of the industrial situation. For detailed discussion of organization, see INDUSTRIAL EDUCATION, also EVENING SCHOOLS.

**Technical Education.** — This entire phase of English Education will be discussed in the article on INDUSTRIAL EDUCATION.

**The Universities and the National System.** — Higher education, in the sense of liberal, scientific, and professional education, is provided in England by universities, university colleges, and professional schools. The modern spirit, the product of liberal ideas of scientific knowledge and industrial demands, is reflected in this higher realm of intellectual activity, not less than in the more extended field of popular education.

In the older universities the process of adjustment to new ideals and demands can be traced from the beginning of the nineteenth century. Science gained special recognition in the middle of the century by the establishment of the Natural Science Tripos at Cambridge, 1851, and the Natural Science Honor School at Oxford, 1853. Notable among the events which mark the changing current of intellectual interests was the founding of a professorship of mechanism and applied mechanics at Cambridge in 1875; the first holder of the chair, Professor James Stuart, established workshops, which afterwards became the property of the university. In these shops practical instruction was given in pattern making, forging, turning, and fitting. About the same time an examination in mechanism and applied science was instituted as one of the special avenues to the ordinary B.A. degree.

The policy of assigning military commissions to university students gave great impulse to studies pertaining to military engineering, military topography, law, etc., and measures were at once taken by both Oxford and Cambridge to adapt the new military courses to the ordinary studies.

Of deeper significance are the movements which grew out of the new impulses in political and social life. The University of London, founded in 1836 as an examining body, was a protest against ecclesiastical monopoly of scholastic sanctions. Two decades later (1854-1857) religious conditions for the B.A. degree were eliminated at Oxford and Cambridge, and, in 1871, when the movement for popular education was at its height, the two universities were freed from all doctrinal tests.

The system of examinations for middle-class schools and individual pupils was the instinctive effort of the universities to extend their sphere of influence throughout the expanding circle of national intelligence. The effort culminated in the university extension movement (*q.v.*), which gave direction to the awakening aspirations of the workingmen of England, and prepared the way for the modern universities.

In the rising regard for education as a national panacea, the interests of women were not ignored. Bedford College for Women, founded in 1849, drew inspiration from London University, and later on, as a consequence of the system of examinations for schools and pupils, Oxford and Cambridge became the seats of colleges for women. In 1878 London University admitted women to its degrees, and in 1895 Durham University took similar action. The Cambridge University Tripos was formally opened to women in 1881, and the Oxford examinations in 1884, but degrees are not conferred upon women students by the two older institutions. (See WOMEN, HIGHER EDUCATION OF.)

The expansion of the university curriculum is not less marked than the widening sphere of university influence. In 1891 Oxford University instituted the degrees of Bachelor of Letters and Bachelor of Science, which were intended to promote and recognize modern studies and intensive research. A doctorate in letters and in science followed. Cambridge University also arranged to admit persons as advanced students and candidates, upon special conditions, for the degree of B.A., and in pursuance of an act of Parliament, 1903, for the regulations of mines, instituted a new diploma in mining engineering. At Oxford arrangements for special studies, leading up, not to a degree, but to a diploma, have increased; among the diplomas recently recognized are those in anthropology and in forestry.

The University of London, reconstituted by statutes of 1900, as a teaching university, is a federation of twenty-six colleges and schools giving instruction in eight faculties (arts, law, medicine, theology, science, engineering, eco-

nomies, and music). The university maintains intimate relations with the municipal system of public education through the council scholarship scheme, which provides the means whereby promising pupils may rise from the elementary school to the full privileges of the higher education. By virtue of an annual subsidy from the council, the latter has the right to nominate a certain number of students to the constituent colleges of the university.

The most impressive fact in the recent history of higher education is the rise of university colleges in the great manufacturing centers. They are the outcome, in part, of private benefactions, and, in part, of municipal enterprise, and their development has been stimulated by Parliamentary grants, annually allowed since 1889. By the federation of the new colleges with older local institutions, scientific and technical, museums, libraries, etc., no less than six universities have been created, each having its distinct sphere of influence. These are Birmingham, Bristol, Leeds, Liverpool, Manchester, London, Sheffield; in addition these are the university colleges of Newcastle (Armstrong College), Nottingham, Reading, Southampton (Hastley College). These regional universities are all essentially modern in spirit and purpose; they offer their facilities on liberal terms alike to men and women, and meet the wants of the artisan classes by their ample provision for evening instruction. They are, as a rule, admirably equipped for technical specialties, and they have, from the first, made unequalled provision for the training of teachers in both the theory and art of their profession. While science and technology were the subjects of the earliest interest with these institutions, they include in their curricula a fair proportion of classical studies, and thus serve to unite scholastic traditions with modern interests.

The realization on the part of these modern universities of their "joint responsibility to the national life," is indicated by the steps they have taken for the common recognition of their various matriculation examinations. The northern universities of Manchester, Liverpool, Leeds, and Sheffield (*q.v.*) have, under their charters, established a joint board which conducts a single examination of all candidates for admission to any one of the four, and seeks to further the movement "for a regular interchange of views, and for the better organization of facilities for advanced study throughout the Empire." (See Table 6, p. 480.)

The importance of the universities, in the increasing scope of public education and of national responsibility in the matter, is recognized by the recent establishment of the Universities Branch of the Board of Education. In respect to this special division it is officially stated: "that the technological and professional instruction (including the training of teachers for elementary and secondary schools) given by the universities and aided by grants from the

Board could not be properly dealt with as part of the ordinary administration of the Board as applied to institutions which have less autonomy, responsibility, and prestige than the universities. The universities need the greatest possible degree of freedom in organizing and carrying out their important national and international functions." In accordance with these convictions, the new division was organized (April, 1910), with Dr. H. F. Heath, Director of Special Inquiries and Reports, as the responsible chief.

By its schemes of scholarship the Board of Education maintains also an open road from the technical and art schools to the Imperial College of Science. This institution is a group of associated colleges, comprising among others the National School of Mines and Normal School of Science (South Kensington) and the City and Guilds Institute. The imperial college was incorporated by Royal Charter in 1907, and was admitted as a school of London University in 1908, but its national character is preserved by the administration of the government scholarships, which draw to this center select students from every part of the kingdom. The Board has recently established special scholarships for teachers of science and technology, who are qualified to enter on the third or fourth year of the course provided at the Imperial College. Thus this central institution will furnish standards and methods for the teaching of these special subjects throughout the kingdom.

**Statistical Summaries.**—The following tables show the scope of the expanded system of public education as presented in the latest official report:—

TABLE 1. — SCHOOLS AND PUPILS UNDER THE BOARD OF EDUCATION — ENGLAND AND WALES.

CLASS OF SCHOOLS	1907-8		1908-9	
	Schools	Enrollment	Schools	Enrollment
Elementary education:				
Public elementary schools . . . . .	20,621	5,984,130	20,699	6,025,163
Certified efficient schools . . . . .	75	4,988	77	5,153
Special schools—				
For the mentally or physically defective . . . . .	190	13,247	215	14,682
For the deaf . . . . .	47	3,421	48	3,468
For the blind . . . . .	39	1,612	39	1,659
For epileptics . . . . .	5	216	5	265
Poor Law schools . . . . .	66	15,470	66	15,470
Higher elementary schools . . . . .	38	8,718	44	9,720
Higher education:				
Evening schools, etc., for further education . . . . .	6,874	751,600	7,153	752,356
Secondary schools . . . . .	840	81,719	912	148,794
Training colleges . . . . .	79	10,492	83	11,372
Technical instruction:				
Technical institutions . . . . .	37	2,863	42	3,400
Day technical classes . . . . .	97	9,029	103	10,277
Schools of art . . . . .	225	41,723	225	42,112
Art classes . . . . .	40	2,493	46	2,660
Total . . . . .	29,273	6,931,751	29,757	7,046,901

ENGLAND

**Public Elementary Schools.**—The public elementary schools included in the foregoing table had an enrollment of 6,025,163 (3,011,699 boys; 2,983,461 girls) pupils, equivalent to 17 per cent of the population; they maintained an average attendance of 5,344,704, or 88.7 per cent of the enrollment. The schools referred to are classified as follows: council schools, corresponding to the former board schools, average attendance, 3,038,204; voluntary schools, which now share in the local taxes, average attendance 2,306,500.

**Teaching Body.**—The teaching force of the elementary schools was as follows:—

TABLE 2.—NUMBER OF ADULT TEACHERS, ENGLAND AND WALES, 1908-1909.

CLASS OF TEACHERS	MEN		WOMEN		TOTAL
	ENGLAND	WALES	ENGLAND	WALES	
Certificated:					
Trained . . . . .	22,640	28,035	50,675		
Untrained . . . . .	9,386	31,712	41,098		
Uncertificated . . . . .	5,668	38,714	44,382		
Others . . . . .	877	19,151	20,028		
Total . . . . .	38,571	129,615	159,186		

Apart from the requirement that the head teacher of a school shall be certificated, the appointment of teachers, their salaries and tenure of office depend entirely upon the local authorities: in these respects there is as wide a range of difference as in the United States. The average annual salaries, in English schools, according to the estimates for 1908-1909, were as follows:—

CLASS	SALARIES			
	Men		Women	
	ENGLAND	WALES	ENGLAND	WALES
Head teachers, certificated:				
Higher elementary schools . . . . .	£318	\$1691	\$215	\$1045
Ordinary elementary schools . . . . .	173	867	120	587
Certificated assistants:				
Higher elementary . . . . .	161	782	111	539
Ordinary elementary . . . . .	124	604	90	457

For uncertificated teachers the average salaries range for men from £43 to £89 (\$215 to \$145); for women, from £36 to £66 (\$180 to \$330).

TABLE 3.—TRAINING COLLEGES FOR TEACHERS, ENGLAND AND WALES, 1908-1909.

CONTROLLING AUTHORITY	COL- LEGES	STUDENTS		TOTAL
		Men	Women

The training colleges are supported by private funds, local appropriations, and government

ENGLAND

grants. The grant in respect of resident students is at the rate of £53 a year for men and £38 for women.

**Cost of Education.**—The sources of income for elementary schools for 1908-1909 and the amount from each source as reported by the local authorities in charge of education are summarized in the following table:—

TABLE 4.—RECEIPTS BY LOCAL AUTHORITIES FOR YEAR ENDING MARCH 31, 1909, FOR CURRENT EXPENSES.

	ELEMENTARY EDUCATION		HIGHER EDUCATION	
	ENGLAND	UNITED STATES EQUIVALENT	ENGLAND	UNITED STATES EQUIVALENT
Residue grants			£829,159	\$4,029,712
Parliamentary grants . . . . .	£11,329,380	\$55,060,786	1,063,628	5,169,232
Rates and borough funds . . . . .	11,162,515	51,249,822	1,768,441	8,591,637
Receipts from local authorities . . . . .	93,214	453,020	197,277	958,766
Fees and sale of books and other articles . . . . .	143,006	695,009	417,135	2,027,276
Endowments . . . . .	217,182	1,055,501	199,336	968,772
Other receipts . . . . .				
Total receipts . . . . .	22,945,303	111,514,172	4,471,983	21,718,417

The relative proportion of the total receipts derived from the chief contributing sources was as follows:—

	ELEMENTARY EDUCATION PER CENT	HIGHER EDUCATION PER CENT
Parliamentary grants . . . . .	49.3	42.3 <sup>1</sup>
Rates and borough funds and receipts from other local sources . . . . .	49.0	44.
Fees and sale of books . . . . .	0.6	9.3
Endowments and miscellaneous . . . . .	1.1	4.4

The total payments in respect of elementary education made by the local authorities, England and Wales, for the year ending Mar. 31, 1909, amounted to £22,795,178, which was £150,125 less than the receipts for that purpose.

The distribution of payments among the different types of local authorities, so far as analyzed, was as follows:—

TABLE 5.—EXPENDITURE FOR ELEMENTARY EDUCATION CLASSIFIED BY LOCAL AUTHORITIES.

TYPE OF AREA OF LOCAL EDUCATION AUTHORITY FOR ELEMENTARY EDUCATION	AMOUNT	
	ENGLAND	UNITED STATES EQUIVALENT
Administrative Counties:		
(a) Areas under County Councils . . . . .	£7,861,261	\$38,206,211
(b) Boroughs . . . . .	2,427,419	10,339,256
(c) Urban districts . . . . .	1,612,941	7,985,707
Total of above . . . . .	11,891,721	56,530,178
London . . . . .	4,308,857	21,232,645

<sup>1</sup>Constituent colleges of the University of Wales.

*Grant-aided Universities and University Colleges, England and Wales.* — The above table pertains to the institutions to which the Board of Education disburses the annual parliamentary grant, amounting at present to £100,000 (\$500,000) for "university colleges in Great Britain," and three colleges in Wales, to each of which an annual grant of £4000 (\$20,000) is made.

The total expenditure for the English institutions in the foregoing table in 1909 was £530,267 (\$2,651,335). Of this amount 26.6 per cent was borne by the government grants; 16.3 per cent by local appropriations; 14.9 per cent by endowments; 32.3 per cent by fees. The corresponding particulars for the three colleges in Wales are: total expenditures, £51,626 (\$258,130), borne as follows: government grant, 39.4 per cent; local appropriations, 8.1 per cent; endowments, 7.7 per cent; fees, 3.9 per cent. The small balance, 11.9 per cent, was derived from other local sources.

**Present Outlook.** — Public education in England, that is, education aided and directed by the State, has been a process of growth fostered by all the forces, religious, social, and political, that have gone to the making of the national life. The Education Act of 1902 embodies the

federation principle that marks the present era, and has brought about the realization of this principle in every order of education, from the elementary school to the university. This is doubtless an effect which will be carried on through subsequent changes of law and purpose as part of the precious heritage of the past. What the next stage in the process will be, so far as it relates to elementary schools, is plainly indicated by the most important event pertaining to them that has taken place since 1902. The opposition to the act of that year culminated in the Education Bill of 1906, submitted by the Liberals and carried by a large majority through the House of Commons. The first clause of the bill provided that: "On and after the first day of January, one thousand nine hundred and eight, a school shall not be recognized as a public elementary school unless it is a school provided by the local education authority." In other words, the bill swept away the dual system of public and church schools, and placed all on the common basis of public control and public support. It was in respect to this clause that the bill was wrecked in the House of Lords. The larger question of the rights of the Commons and the restriction of the authority of the Upper House, now pending, carries with it, by common admission, the resettlement of the education question on the basis of the defeated bill. Practically all the other important provisions of that measure have been secured either by the subsequent acts already referred to, or by orders of the Board of Education, as in the case of the separate administration for Wales.

It is a significant fact that, while the bill of 1906 refused to recognize church schools, it made ample provision for religious instruction in the schools, and even for sectarian teaching under due safeguards. The debate over the measure proved that England was not prepared at that time for a system of education purely secular; but at the same time the opposition to government support for denominational teaching was intense. So far as possible, the will of the Commons in this respect has been carried out by subsequent regulations of the Board of Education. They have opened secondary schools to aspiring students, irrespective of their religious tenets, and they have required that in every training college at least half the number of vacant places in each year shall be filled under the same conditions. The result is that, in addition to the 7000 places in undenominational colleges, half of the 5000 places in denominational colleges are at present free from religious tests. These provisions illustrate the spirit of compromise which has marked the gradual progress of popular government in England. Never before in that long history were the democratic forces so strong and so well organized as at the present time; the Education Bill of 1906 embodied their mandate with respect to public education, softened by regard for all the pre-

vious inheritance from the past. In this particular the author of the bill, Rt. Hon. Augustine Birrell, at that time President of the Board of Education, was more conservative than the party which he represented. The unswerving adherence of that party to the principle of civic control was emphasized by the McKenna Bill, submitted to the House of Commons Feb. 24, 1908, but speedily withdrawn in view of the certainty of disagreement between the two Houses. The same course was taken with a substitute measure introduced later in the year (Nov. 20) by Mr. Runciman, who had succeeded Mr. McKenna as President of the Board of Education. Subsequent events have deferred Parliamentary action in this matter; but meanwhile, as a result of the united efforts of Mr. Runciman and the Archbishop of Canterbury, supported by eminent men and women of both parties, a committee has been formed for the purpose of devising a plan for "resettlement in English elementary education." This committee concedes the principle of public control for public schools, and of absolute religious freedom for the teachers. Their plan provides, however, for local option in respect to the continuance and support of denominational schools according to the choice of parents.

Notwithstanding, therefore, the increasing unity of educational aims, the common recognition of urgent problems of continuative education, of vocational training, of rural education, the paramount question in regard to this interest in England is still that of the local administration and support of elementary schools. Second only in importance to this interest is that of the authority of the Board of Education, which has been steadily increasing since its creation in 1899. This authority, however, bears no resemblance to the absolute dictum of a centralized authority like the French Ministry of Public Instruction. It rests upon the voluntary assent of civic or institutional authorities, desirous of sharing in the treasury grants or of promoting unity of aim and economy of resources through a national agency. All government measures are closely scrutinized by local authorities intolerant of any encroachments upon their rights, and are subjects of keen analysis and criticism by the numerous educational associations for which England is noted. Apart from their mastery of professional problems, these associations exercise great influence either by their political affiliations, as in the case of the National Union of Elementary Teachers, or their social affiliations, as in the case of the Association of Headmasters, or by their effective organization of popular opinion, as illustrated by the North of England Education Conference.

The education system, like the national life of England, not only progresses by compromise, but holds to what is enduring by a marvelous system of checks and counterchecks.

**ENGLISH LANGUAGE AND LITERATURE.**—This subject is treated in its various aspects under the appropriate captions. The principles underlying the development and present structure of languages in general and of the English language in particular, together with the essential facts in its historic development, are given under PHILOLOGY, and LANGUAGE, ENGLISH. A further treatment of historic aspect of the topic will be found under ANGLLO-SAXON. Under the title GRAMMAR, ENGLISH, will be found a statement of the history of the scientific or logical study of language structure and usage, especially as it has affected the schools. The question of usage is further treated in regard to underlying principles in the following article on ENGLISH USAGE. Educational practices and conditions relating to training in usage are presented in the article on COMPOSITION; the academic relations of English are dealt with under the title LITERATURE, ENGLISH. Related to certain aspects of the subject are the special articles on LITERATURE, CHILDREN'S, and LITERATURE, COMPARATIVE. The problems

relating to the teaching of English in American secondary schools are stated in the article on COLLEGE REQUIREMENTS FOR ADMISSION. Various topics relating to method are treated more fully under the caption, READING, TEACHING OF, and under the various special topics relating to method. The place of English language and literature in foreign schools will be considered under the caption MODERN LANGUAGES IN EDUCATION, and also, so far as the place in the curriculum is concerned, in the articles on the educational systems of the various countries. Appropriate lists of references to the literature of the subject are given in connection with each of the articles mentioned.

**ENGLISH LANGUAGE, TEACHING OF.**—SEE COMPOSITION; ENGLISH GRAMMAR.

**ENGLISH LITERATURE IN THE SCHOOLS.**—SEE LITERATURE, ENGLISH.

**ENGLISH METHOD IN READING.**—A special system for teaching beginners to read, considerably used in England during the last quarter century. It was embodied in a set of three small volumes issued by Messrs. Meiklejohn and Sonnenschein. The main idea of this special arrangement of reading rests upon a classification of the reading words to be used by children into two groups: (1) those words with a regular spelling where each letter has a single value or function, and (2) those in which the symbol may stand for several sounds, or in which several symbols may represent a single sound. All the earlier reading work is to be confined to a use of material of the first class. Only after considerable acquisition of reading power would the child be brought into contact with anomalous spellings. H. S.

SEE READING, TEACHING OF.

**ENGLISH SPELLING.**—SEE SPELLING.

**ENGLISH USAGE.**—Questions of usage are the most persistent, and generally the least satisfactorily answered, of all that arise in the practical study and teaching of language. They occur in connection with all the various aspects of language, but whether the question is one of concord or morphology in grammar, of the quality of a sound or of an accent in pronunciation, or of the spelling of a word in writing, the same general principles are involved. All those aspects of language which tend to become systematic and formal inevitably give rise to questions of usage. Much of the uncertainty in answering these questions is due to a lack of clear distinction between two different ways of regarding language, the one being concerned with the manner in which system or regularity develops in speech, the other with the value and consequently the justification of deviations, or apparent deviations, from the regular.

It is obvious that use or custom is the most powerful influence in bringing about system and regularity in speech. No external authority has the power to impose a system of grammar upon a language which practical use merely exhibits in daily conversation and writing. Nor again is there any ground for supposing a kind of inherent organic nature in a language which develops, or evolves itself, through the medium of actual practice. Speech grows, as social custom grows in other ways, through the tendency of human beings to imitate each other and to become alike in their social acts, and thus to unite themselves in groups. Regarded in this way, the usage of a language may be defined as the customary practice of a given group of people with respect to the social activity of speech. This is manifestly a broad definition, and covers all the activities of language, but it is only by looking at the matter from this comprehensive point of view that a sound practical approach to the specific questions of usage can be made.

Usage as thus defined does not arise in a single and uniform way in a speech. Strictly speaking, perfect uniformity does not probably exist between any two speakers. Individual differences are inevitable, due to the different physical and mental constitutions of any two individuals. There is, however, in all practical use of language, what might be called an area of negligible variation. Practical speech does not demand absolute uniformity, since only an approximately uniform use is necessary to intelligibility. Consequently we make allowance for differences, and assume that those speakers who, in the main, speak as we do, belong to our group. There arise thus what are technically known as dialects. In the popular sense of the term, dialect means the speech of a local, or somewhat illiterate section of the public, which differs from and is less admirable than the so-called standard speech. Scientifically, however, dialect means merely the speech of a group of people which has sufficient homogeneity to enable the members of the group to realize themselves as parts of a speech unity, and which enables the descriptive student of the dialect to state its characteristics in a way which distinguishes it from other unified speech groups. Thus the scientific student of language speaks of the Indo-European dialects, meaning thereby the various speeches of Europe and Asia which belong to the general Indo-European family of languages. In the same way, he speaks of the Germanic dialects, meaning the various Scandinavian, German, and English idioms which have similarities enough in common to show that they all belong to one general branch of the Indo-European family, but also distinctive differences enough to justify the student in regarding each as a separate and homogeneous unity. Continuing this method of differentiation, we can

speak of the English dialects, meaning thereby those different forms of the English speech which differ among themselves, but which also resemble each other sufficiently to justify us in holding them together as one speech.

Now it is obvious that the area of negligible variation must be increased in proportion as one extends the limits of inclusion within a single speech, or within a branch or family of languages. In order to assume the existence of a single, unified English speech, it is necessary to overlook all the many distinctions which go to make up individual and local modes of speech. And if we include English, German, and Scandinavian as members of a Germanic branch representing a unified parent Germanic, it is manifestly necessary to allow for many more discrepancies between the various members of the branch.

This prepares the way for a definition of standard speech. A standard speech is the sum of those similarities among the different members of a speech community, which together constitute the grounds for assuming the existence of a uniform and single practice in the speech. In this relative sense the term "standard" must apply to the practice of everybody who uses any form of the speech; and the broadest English standard would consequently have to include the speech of Englishmen, Americans, Australians, Canadians,—of every individual who anywhere spoke what might justly be called a form of the English tongue. Or standard English might be limited indefinitely, to include only the speech of America, or of Virginia, or of Chicago, or of "educated" as contrasted with "uneducated" speakers, or "good" society as contrasted with "vulgar" society, and so forth, without end. It should not be overlooked, however, that any such standard speech is theoretical, and if the statement made above is true that individual variation is permanent, a standard speech always must be a theoretical idea. In other words, a standard speech is a theoretical norm established by an artificial grouping of similarities, and is not, in any scientific understanding of the processes of language, either the authorized edict or practice and example of any individual or group of individuals. It is a further corollary of this definition of standard speech, that the more inclusive the standard, the less intimate and personal, and the more general and conventional, are the ideas and feelings which can be expressed by the forms of language which are subsumed under the theoretical unity of the standard. The elements of the English language, for example, which are common to the whole race of English-speaking people, would hardly be adequate for more than the simplest and most colorless kind of intercommunication. In character it would approach an artificial language, and of course an artificial language it would be. Indeed, one of the most recent and

best of artificial languages, Ido, is constructed on this principle of forming a standard European speech by grouping into one speech those elements which are common to all or to the greatest number of the languages of Europe.

Practically the question of standard is often approached by an arbitrary assumption of the right of one particular group of speakers to represent this theoretical standard of which we have been speaking. In countries and periods in which royal authority counted heavily, it was often assumed that the court best represented the standard speech. Often also a capital city, as the center of civilization in the country, was assumed to give in the speech of its citizens the model for the rest of the nation, as Paris is supposed to do for France. Or again the speech of a particular class of society has been frequently taken as summing up the general and standard characteristics of the speech. In our day, owing to the important position which formal education occupies, the practice of the "educated classes" becomes the theoretical standard. Whatever the standard chosen, however, whether it be a geographical, a social, or an educational standard, it should be observed that the choice rests entirely with the individual, and is determined by his own powers or experiences in observation and by his own predilections after he has made his own observations. The assumption of any one standard as absolutely right and to be imposed upon all users of the language is obviously a piece of sheer dogmatism which could be carried into effect only by the exercise of an autocratic authority of a kind such as the English language has never submitted to. It is hardly necessary to state that dictionaries have no such authority; at their best they are merely a summary of the widest national or international use of the language, but a summary which in the nature of things cannot be contemporary. Language changes from day to day, but dictionaries change not at all, or only at long intervals.

Such being the manner of the establishment of standard or customary use, the second question is one of values in determining actual practice in language. By the circumstances of birth, education, and environment, each individual is naturally and necessarily provided with a form of speech which is general or standard within its group. The unthinking person, or the one whose mind is never projected outside his group, never calls in question the forms of his natural speech. But the person who finds his speech in conflict with that of some other person, or group of persons, whether the differences be due to geographical or social causes, is bound to consider the value of his own as compared with the other speech. In other words, there arises then a question of divided use, or a conflict of standards, and manifestly the first necessity is to determine the value of the

standard which one wishes to apply as regulating practice. It is equally manifest that no single prescription can be given determining the values of different standards. It cannot be said that the most general, international usage in English is thereby absolutely the best, since there are many occasions, for example the familiar conversation of daily life, in which the formal, general standard would be inappropriate. Likewise it cannot be said that the strict rules of formal grammar are best and right merely because they are accepted in theoretical descriptions of the language, and that deviations from the strict system are wrong, even though they may be current in the colloquial practical use of the language. Rhetorical and other books contain many dogmas, for example the rule against the split infinitive, against ending a sentence with a preposition, etc., which are often contrary both to practice and effectiveness in language. In default of any abstract or absolute test of value in usage, the only method left is a relative and practical one. The only general rule that can be given when a question of choice between two uses in language arises, is to choose the form or use which will most effectively attain the end which the person seeks to attain upon whom the necessity of choice falls. If through habit a speaker is accustomed to use a form like "He don't," and is then confronted with the statement of grammars and also the practice of many speakers who use the form "He doesn't," he must decide for himself whether the use of his habitual mode of speaking operates to his disadvantage, and if so, whether it is worth his while to acquire a new habit. The purpose of language being to convey certain ideas from one person to another, the use of language should be determined by its adequacy to attain this end. Any forms of language which for any reason whatever, either explicitly or implicitly, convey ideas which the user of these forms did not intend to convey, is in so far an inadequate use of language, and should be corrected by a more effective application of standards of value in the use of the language. It is true, however, that language exists not only for purposes of intercommunication, but also for purposes of individual self-expression; and a speaker may prefer to use a form of language which satisfies his own sense of the proper and effective, even though he knows his language will not carry his message to the person whom he is addressing. In such instances the speaker must be content with having satisfied himself, and must not complain of the inadequacies of speech, unless he is quite sure that the language does not provide what can satisfy his hearer as well as himself in the expression of what he would say.

**ENLIGHTENMENT AND EDUCATION.**—“Enlightenment” is a term that is used to characterize the particular phase of philosophical speculation which falls in the main within the period of the eighteenth century. Beginning in England, this movement of thought spread to France and Germany, under the names, *l’Eclaircissement* and *die Aufklärung* respectively. This name, whether in its English, French, or German form, serves to picture to our minds the essential characteristics of an age which sought its illumination in the light of reason, while authority and tradition were assigned a place of secondary consideration, or else discarded altogether. There was a demand in this period for the free play of the individual judgment, and an accompanying protest against all abstruse metaphysical speculations which endeavor to transcend the normal and usual processes of reason. All investigation, it was insisted, must begin with the interpretation of our ordinary experiences, according to our knowledge of the natural causes underlying them. The age was individualistic and naturalistic, magnifying the present and scornful of the past. Its influences were not confined simply to the sphere of the schools, nor were its interests purely speculative. Its philosophy had its practical outcome as well, and profoundly affected the life of the people, on its religious, moral, and political side. The theory and practice of education were not free from the influences of these characteristic tendencies.

Educationally the Enlightenment helped to reinforce the acceptance of education as a discipline for the development of the reasoning abilities. At this period, perhaps, more than ever, the child was regarded as an adult in miniature. Hence the same kind of formalism was expected from the young as from the old. In school practice it is difficult to dissociate the influence of the Enlightenment from the disciplinary tendency in education. Locke (*q.v.*) may be taken as an early representative of both movements, just as Rousseau and the naturalistic movement represent the individualistic tendency, which resulted from the Enlightenment. Since the Enlightenment affected educational practice only by presenting a new aim, the development of reason, to which the existing curriculum was to be directed, it did not involve the introduction of a new type of institution. The general bearing of the entire period will be discussed more under ROUSSEAU and the NATURALISTIC MOVEMENT IN EDUCATION. J. G. H.

**ENRICHMENT OF THE CURRICULUM.**

—The process of expanding the course of study so as to include a wider range of activities. The movement for the enrichment of the curriculum has been a characteristic expression of school reform during the latter part of the nineteenth century. It has had its largest influence in the elementary school. Enrichment does not merely refer to the addition of new school subjects; it includes the reform of the older subjects. It has expressed itself in the addition of an abundance of content in the traditional formal subjects, and in the increased use of concrete and active methods of learning. The whole tendency has been in the direction of augmenting the curriculum with experiences and activities that would be more varied, natural, useful, and interesting. H. S.

**ENROLLMENT.**—See RECORDS AND REPORTS.

**ENTRANCE REQUIREMENTS.**—See COLLEGE, AMERICAN, REQUIREMENTS FOR ADMISSION.

**ENUNCIATION.**—The act of enunciation or utterance is frequently an object of special drill in the teaching of reading, more particularly with beginners in reading. The aim is to gain a distinct pronunciation. Various devices are used in these enunciation drills, such as phonetic spelling, syllabification, word building, etc. H. S.

See READING, TEACHING OF.

**ENVIRONMENT AND ORGANISM.**—These terms are as strictly correlative as are brother and sister, buyer and seller, stimulus

and response. Wherever there are correlative terms, there is a third medium to which both refer. In the case of organism and environment, this more comprehensive matter is life as a self-conserving, expanding activity. (See FUNCTION.) Life is a process which includes environment as well as organism within itself; if we are apt to connect life with the organism and not with the environment, this only means that its connection with the former is direct, and with the latter indirect, or by means of the organism. But this indirect connection, when examined, is readily interpreted to mean that the organism itself is only a device for making the environment an included part of a life activity. We shall first expound the meaning of this formula of the subordination of both organism and environment to life or function; and then apply the results to educational theory, in which the school as an institution represents the environment side and the pupils the organism side.

The environment of any organism consists of the sum total of conditions that enter in an active way into the direction of the functions of any living being. Environment, therefore, is not equivalent merely to surrounding physical conditions. There may be much in the physical surroundings to which an organism is irresponsible; such conditions are no part of its true environment. Whatever affords it food, whatever threatens it, whatever protects it against menace, whatever operates as signal to direct it toward food or a mate, or away from an enemy,—such conditions are true constituents of its environment. Consequently environments change with the development of the organism, individual and racial. The young of a species react to fewer and more generalized stimuli, as a rule, than the mature specimens of the same species. The lower forms of life are so undifferentiated in their functions that they have a comparatively homogeneous environment, living for the most part in a liquid medium, and reacting only to a few simple mechanical and chemical changes. As organisms grow, and their functions are differentiated through special structures to exercise each, the environment gets correspondingly heterogeneous and complex. With free locomotion and a nervous system the environment comes to include great stretches not only of space, but of time, since by retention and memory the animal becomes capable of reacting to conditions of its past life. There is, then, a genuine sense in which the evolution of life, the increase in diversity and interdependence of life functions, means an evolution of new environments just as truly as of new organs.

The greatest change of environment occurs when living beings become conscious of the fact that their reactions to preëxistent stimuli modify the old forms in such a way as to create new or different stimuli. When living beings

become aware of this fact, modification of the environment for the sake of getting stimuli that will make the exercise of functions more secure, more effective, and freer, becomes a deliberate end. This transformation is familiar to us in the form of the tools, the utensils, weapons, devices of all kinds, by which man consciously modified the environment in the interest of the exercise of his own life activities. In this way, some parts at least of the environment become what have been called "extra-organic" organs; that is to say, all the tools and devices of all the arts, although outside the body, operate in behalf of the functions of life just as do the eye, stomach, hands, etc. From this biological point of view, deliberate or conscious behavior is just a way of doing more effectively and economically what unconscious life adaptations do in a relatively wasteful and uncontrolled way, namely, modifying the environment so as to make it a more varied and more stable or secure stimulus for the exercise of functions.

A part of this work of transforming the environment in the interests of life has to do with selecting and maintaining the environment which is best adapted to promote the growth of the young or immature towards full participation in the life activities of the community to which they belong. This specially adapted environment constitutes the educational agencies which a given community employs. The community, in order to maintain its own life, must control the direction taken by the growing capacities of all its immature members, since in time these will replace the mature members, and hence constitute, in turn, the community. No such thing as purely direct control is possible, however. Control of direction of growth must take place indirectly through selecting and loading, as it were, the stimuli which evoke responses and hereby determine habits. In simple, savage groups, the existing habits of the elders are enough to give such direction; direct participation and reproduction in play suffice for the required development. As a society gets more complex, and its arts more elaborate, a special environment has to be provided, and the school as a special institution comes into existence. From the biological standpoint, accordingly, the school with all its subject matter, apparatus, and guiding personalities (teachers, etc.) constitutes a set of specially selected and arranged stimuli for the sake of evoking and forming certain standard types of response on the part of the life functions. J. D.

**EPICETETUS.**—Stoic philosopher and teacher; born at Hierapolis in Phrygia about the year 60 A.D. In his early life he was the slave of Epaphroditus, one of Nero's courtiers, who treated him cruelly, but, perhaps in expiation of his severity, permitted him to attend the lectures of Musonius Rufus. Later, by what means is not known, Epictetus obtained his freedom and himself became a teacher of the Stoic philosophy. When, in the year 90 A.D., the philosophers were banished from Rome by decree of Domitian, he removed to Nicopolis in Epirus, where he continued to teach for some years. He was highly esteemed, both for the nobility of his character and the spirit and content of his teaching. He wrote nothing himself, but his discourses and conversations were taken down by his pupil Arrian and published in two treatises,—*The Discourses (Diatribai)*, and the *Manual (Enchiridion)*. Epictetus accepted the Stoic doctrine of natural or innate moral principles, the superiority of reason to all other faculties, and the supremacy of the will. "The nature and essence of the good is in a certain disposition of the will; likewise that of the evil. What, then, are outward things? Matter for the will, about which being occupied, it shall obtain its own good or evil." We cannot choose the ideas which present themselves to us, and we must accept events as the pervading reason of the universe determines them, but reason should rule among perceptions, and the will should placidly assent to whatever fortune the God immanent in nature sends. Even death itself is nothing terrible to the wise man. The aim and spirit of education as conceived by Epictetus may be thus stated in his own words: "And now I am your teacher and ye are being taught by me. And I have this aim—to perfect you, that ye be un hindered, uncompelled, unembarrassed, free, prosperous, happy, looking unto God alone in all things great and small." Of the eight books of the *Discourses* collected by Arrian, four have been lost. The extant works have been translated and published in English in various editions.

**EPICURUS** (341–270 B.C.).—Greek philosopher, the son of an Athenian schoolmaster; born on the island of Samos in 341 B.C. He claimed to have been self-taught, but evidently had some training in the philosophy of Democritus and other previous systems. He first taught in Mitylene and Lampsacus, and in 306 established himself in Athens. Here he purchased his famous Garden to the northwest

of the city on the road to the Academy, and in it opened his school. Even women and slaves were admitted, and proselytes were rapidly added, as much through the personality of the founder as the popularity of his doctrines. Epicurus never married, and took no part in political life, but in happy seclusion devoted himself to the development of his philosophy. He was revered almost as a god by his followers, and his system was never changed in any of its essentials. His health was always feeble, but he lived until his seventy-second year (270 B.C.). By his will he left the Garden to the successive heads of the school.

Epicurus wrote voluminously upon ethics, physics, and theology, producing some three hundred rolls. His work *On Nature* alone was said to have filled thirty-seven rolls. Selections from his teachings, known as *Golden Maxims*, were handed down from generation to generation, and the *Letters* to and from his friends were preserved for several centuries. All his writings, however, except the *Maxims* and three of the didactic *Letters*, afterward disappeared, although parts of his treatise *On Nature* have been recovered from Herculaneum. The chief sources of our present knowledge of his system are found in Book X of Diogenes Laertius, *Lives of the Philosophers*, and in the poetic descriptions of Lucretius. *On the Nature of Things*. The philosophy of Epicurus, like that of the post-Aristotelian period generally, was an outgrowth of the collapse of Greek life. It centered about ethics, but failed to emphasize participation in social life as essential to the individual. Epicurus agreed with the Cyrenaics in making pleasure the goal. While he could not conceive of happiness altogether apart from bodily enjoyment, unlike Aristippus, he emphasized duration and permanency, rather than intensity, of pleasure. He disparaged all positive pleasures as compared with a philosophic poise of mind, advocating an independence of the world and a freedom from emotion (*ataraxia*, imperturbability). "If thou wilt make a man happy, add not unto his riches, but take away from his desires." While pleasure with Epicurus was chiefly mental, it consisted in repose and pleasing conversation with friends rather than strenuous study. He regarded as superfluous all knowledge that did not promote happiness, and rather deprecated culture and the current education. Hence the atomistic physics of Epicurus, which has sometimes given him the reputation of being "the first scientist," was merely ancillary to his ethics, and was for the most part borrowed from Democritus. Epicurus attempted a scientific explanation of the universe only so far as this might rid one of religion, which he considered the greatest foe to peace of mind. He wished to substitute a purely natural and mechanical interpretation for the idea of a world ruled by gods, who must be propitiated. He explained the con-

stitution of the universe by "atoms" and the space in which they move. All things were formed by the impact and combination of an infinite number of indestructible atoms. Even the soul is composed of finer particles, and these are scattered after death. Freedom of the will, which was required by his ethical doctrine, Epicurus saved by modifying the "necessity" and mechanical law of Democritus with an imperceptible "swerve" and spontaneity in the atoms.

The philosophy of Epicurus appealed strongly to the times. For two centuries it spread rapidly through Greece, Italy, and even the barbarian world, although there was occasionally much resistance on the score of effeminacy and irreligion. The Epicurean opposition to culture also kept its doctrines from wide acceptance in Greece, but from their practical nature they found a congenial soil in Rome, where they were introduced about the middle of the second century B.C. Epicureanism was chosen as a theme by a multitude of Roman writers, including the celebrated Lucretius, and the works of Catullus, Vergil, and Horace attest its influence. The emperor, Marcus Aurelius, in 176 A.D., put the Epicurean school at Athens upon a footing of equal endowment with the three other post-Aristotelian schools, and, according to Diogenes, it was still in existence as an organization a century later. During the Empire, Epicureanism was perverted to the luxuriousness of the times, and, by the beginning of the Middle Ages, had faded away, except as a term of reproach. With the awakening of natural impulses and the joy in living of the Renaissance, the Italian humanists, such as Petrarch, Boccaccio, Bruni, Guarino, Vittorino, and Valla, show decided views of Epicureanism in their educational theories and practices. In the upper countries this departure from medieval asceticism and otherworldliness becomes more marked in the pedagogy of the humanists, Erasmus, Elyot, and Aseham; of the reformers, Luther, Melancthon, and Neander; and especially of the realistic innovators, Rabelais and Montaigne. In the seventeenth century Epicureanism was revived as a regular system by Gassendi, and for a time found many advocates. During the eighteenth century Epicurean tendencies are discernible in the brilliant rationalism of Voltaire and the Encyclopedists, and in Rousseau's summons to return from the artificialities of civilization to nature and natural pleasures. In the nineteenth century a suggestion of Epicurus is found in Bentham, with his pleasant retirement, his foundation of morality upon an intelligent basis of fact, and his careful calculation of pleasures. There is some similarity, too, in Comte's relations with his pupils and admirers, and in certain aspects of his positivistic philosophy, while the "higher pleasures" of Spencer's utilitarianism remind one strongly of Epicurus.

#### EPIDEMICS AMONG SCHOOL CHILDREN. — See CONTAGIOUS DISEASES.

**EPILEPSY.** — A name given to a disease or a series of diseases that in their symptomatology closely resemble one another. All kinds of epilepsy have in common suddenly appearing attacks. A common, but by no means a constant, symptom is a series of convulsions which involve the whole or large areas of the body. All convulsions, are, however, not necessarily epileptic in character. The hyperkinetic phenomena attending intoxications, the seizures accompanying certain brain diseases, and the tonic and clonic spasms accompanying other bodily irritations are rather epileptoid than epileptic (see CONVULSION). The true, or so-called idiopathic, epilepsy may be due to different causes, and may, etiologically considered, be a number of diseases. The pathology of the true epilepsies has not been satisfactorily determined, but at times distinct cerebral lesions have been discovered to be associated with the condition. The causes of epilepsy are only vaguely known. Heredity appears to play an important part, for it is found that many epileptics have among their forbears individuals similarly affected, or hysteric, or with other psychoneuroses.

It has, however, been noted that the convulsions in early childhood, those due to eclampsia and to digestive and dentition disturbances, are sometimes followed by real epilepsy, which begins at about the age of puberty. It is also found that children with night fears, with nocturnal enuresis, etc., often fall into an epileptic state at the critical period of puberty, and the early phenomena are supposed to bear some relation to the later convulsive attacks. The idiopathic epilepsy begins before the age of thirty, most of the cases developing near the pubertal period. The two sexes are equally affected, although uterine disease is given as one of the causes by some authors.

The development of the epileptic condition is so often found to be associated with general bodily disturbances, such as the intoxications from alcohol, lead, morphine, and other narcotics, and with a general irritability due to local conditions, such as eyestrain, decayed teeth, intestinal parasites, nasal growths, etc., that these are usually considered to be exciting

causes. It may be said that any bodily disturbance may bring about a convulsion, if the nervous effect of the disturbance be a prominent feature of it. The nervous factor is undoubtedly the important one. In fact, it has been found that the initial epileptic attack has been produced by mental injuries alone. The epileptic attack may take one of three forms: grand mal, petit mal, and the psychic equivalent. The grand mal type is common, and consists of violent motor disturbances; the petit mal type is often associated with the grand mal, and consists of temporary unconsciousness with slight or no motor hyperkinesis; and the psychic equivalents are less frequent than either of the other types, and consist of mental derangements of a periodic and temporary character.

It is almost impossible to describe the psychic equivalents of epilepsy, on account of their great variety and their inconsistency. They usually consist of the performance of abnormal acts, including speech, with an amnesia for the period during which the attack persists. During such an attack an individual may assail, and even kill, a friend, may become capricious and indecent, and in general do all kinds of unlawful acts. This condition may last for only a few minutes or hours, or it may continue for several days, to be followed by a normal period with an amnesia for the time of the attack. It is of interest to note that migraine is believed by some authors to be a sensory equivalent of epilepsy.

Improvement, sometimes recovery, takes place when all sources of irritation are removed and good hygienic surroundings are provided. The best care and the best conditions are not to be found outside of special institutions, and it is to the interest of the individual and of the community that such patients should be segregated. Under no circumstances should a child with epilepsy be permitted to remain in the same class with otherwise normal children, for the power of suggestion is so great that the sight of a convulsion may start a psychosis in individual children or in the group. (See HYSTERIA.)

Mentally, epileptic children may be bright, even abnormally so, but usually they are dull and behind the children of their age. The periods of confusion and of stupidity following convulsions make the child unfit for any mental work, and there is produced a condition of retardation on account of the loss of instruction and of the inability to make up the lost time. This is an added reason why such children should be segregated, for their mental wants may be best taken care of where their mental and physical conditions are best understood.

**EPIPHANIUS.**—One of the most learned men of the fourth century, born in Palestine about 315 A.D. and educated in the Hebrew schools. He spoke five languages, Hebrew, Syriac, Egyptian, Greek, and Latin. For the last thirty-six years of his life he was Bishop of Salamis in Cyprus. He was an ardent promoter of monasticism, and a doughty antagonist of the philosophic treatment of the Christian faith, which most of the Greek fathers regarded with favor. He was a fanatical opponent of the theology of Origen (*q.v.*). His learning was encyclopedic, but not exact. As a writer he was uncritical and credulous, but we are indebted to him for the preservation of many valuable fragments of ancient writings and traditions. He regarded it as his life work to defend the Christian faith by combating heresy in all its forms. He has left us two great polemical treatises: the *Anchoratus*, in which he strives to "anchor" the Church by defining the true faith; and the vast *Panarion*, a "medicine chest" of remedies for all the poisonous forms of error, in which he describes and refutes eighty different heresies and wins for himself the designation, "the sleuth-hound of heresy."

**EPIPHENOMENON.**—This word is frequently used in psychological discussions, where it is pointed out that consciousness cannot be treated as a cause in the same sense that physical energy can be treated as a cause. Since consciousness is not a cause to be reckoned with in physical formulas, it has sometimes been regarded as the mere reflection of reality, not affecting the world in any wise, but simply appearing as the parallel of the real facts of the physical world. Such a view relieves the psychologist from the task of showing a definite causal relation between mental processes and physical processes. As a theoretical device it has been of some value. It has, however, complicated discussions of consciousness by rendering obscure the causal concept and mystifying many readers who recognize consciousness as the most obvious fact in experience, even though it is a type of reality which cannot be included in physical formulas.

**EPISCOPAL SCHOOLS.**—See BISHOPS' SCHOOLS; CHRISTIAN CHURCH; CHURCH SCHOOLS, etc.

**EPISCOPAL THEOLOGICAL SCHOOL, CAMBRIDGE, MASS.**—A school for the education of young men for the ministry of the Protestant Episcopal Church, opened in

1867. Candidates for degrees in divinity must present a college degree on entrance, and all candidates must have a knowledge of Greek, although facilities are offered for special students. The students enjoy certain privileges at Harvard University.

**EPISTEMOLOGY.**—The theory or doctrine of knowledge; more especially, an account of the possibility of true or valid knowledge, of its nature and extent or limits. In Greek thought this discipline, as distinct from logic and psychology, can hardly be said to have existed. The Greek mode of approach was objective; it conceived of knowledge, whether true or false, as a relation or function of things of different sorts. True knowledge was due to the operation of stable, universal, self-consistent being; falsity to an intermixture of becoming, non-being, particularity, and mere potentiality. Thus questions as to the nature of knowledge were distributed between logic and metaphysics. Even so far as questions arose as to the respective values of sensation and reason in purveying knowledge, sensation and thought were conceived of not as powers or states of individual mind or consciousness, but as ways in which things manifested themselves. In both Plato and Aristotle, mind and all conscious operations were thought of as perfections, as completions, of objective existence, not as the original data from which a discussion of knowledge must set out.

Epistemology as a distinct branch of philosophy developed out of the growth of individualism. The tendency of nominalism was to make mind or consciousness a possession of individual selves or souls. Then it naturally became a problem how the individual could get outside of himself to know an exterior world. The problem was accentuated by the development of physical science. In Greek thought there was no sharp distinction between physical and ideal (mental and moral) characteristics, for the objective world was regarded as one of *qualitative diversities*. Under the influence first of Neo-Platonism and then of Aristotelianism, scholastic philosophy had recognized a graded, or hierarchical, order of qualitative values, up from "first matter," which had least of ideal quality through an ascending hierarchy of existences, up to God as pure intelligence and love. But when physical science reduced the seeming heterogeneity of the objective universe to homogeneity, finding but one kind of matter and one type of motion throughout its entire extent, the objective world was inevitably conceived of as marked only by mechanical and quantitative distinctions. Not only was it stripped of moral and æsthetic values, but of odor, color, sound, etc. Another place or abode had then to be found for all distinctions of value and quality. Mind or consciousness was natur-

ally taken as their seat or residence. The classic antithesis of mind as ideal and teleological, and matter as brute, inert, anti-purposive, was now identified with the difference between the knowing mind and the objective world known. From this dualism, practically unknown to either the Greek or the medieval world, modern philosophy in Descartes and Locke sets out.

Given, then, a knower who is purely individual or "subjective," and whose being is wholly psychical and immaterial (all qualitative differences being psychical and immaterial), and a world to be known which is purely universal or "objective," and whose being is wholly mechanical and physical, the problem of how knowledge is possible is an inevitable one. Knower and known being conceived in absolutely opposed terms, the question arises as to *how* and as to how *far* the gulf between them can be spanned—for knowledge clearly implies that the gulf is spanned. All that portion of modern philosophy which discusses the possibility, nature, and limits of knowledge, or the basis of these presuppositions constitutes Epistemology. Various modes of solution constitute the various forms of realism, idealism, phenomenalism (*qq.v.*), current in modern philosophy.

A marked tendency of existing thought is giving up the attempt of a search for a solution, not on the ground that the problem is insoluble (philosophic agnosticism), but on the ground that it is artificial. In other words, there is a growing tendency to question the sharp setting over of the individual self against nature, and of the qualitative and ideal phases of existence against its quantitative and mechanical traits. The theory of evolution (*q.v.*) with its insistence upon continuity has doubtless been the chief cause from the scientific side of this changing attitude, while from the philosophic side the more careful analysis of experience (*q.v.*) has led to the view that the distinctions of the individual and the universal, the psychical and the physical, the natural and the ideal, are distinctions of functions of existence rather than of structural elements of existence. J. D.

**EPISTOLÆ.** — The art of letter writing was cultivated as an educational method in the sixteenth and succeeding centuries. Of all written methods, it was supposed to approach nearest to the use of the Colloquy, which was the simplest step to take in teaching Latin speaking (see COLLOQUIES). Latin letter writing thus was helpful for written composition and also for providing material in Latin conversation. John Brinsley (*q.v.*) in his *Ludus Literarius* devotes a chapter to the "making epistles imitating Tully" (*i.e.* Cicero). He says epistles should be "short, pithy, sweet Latin, and familiar." The master's method was to read to the pupils Cicero's *Epistles*, and some part of Macropedius or Hegendorphinus' *De Conscribendis Epistolis*. The rules laid down in those authors, says Brinsley, were to be explained and the examples made clear. The boys were to be informed that an epistle is nothing but a letter sent to a friend, "to notify him of some matter or to signify our mind plainly and fully unto him." Brinsley requires practice in imitating Cicero's *Epistles*, and in framing answers to his letters, first in English, then in Latin. Charles Hoole (*q.v.*), in his *New Discovery of the Old Art of Teaching School* (1660), writes with still fuller directions — giving model examples of boys' imitations and adaptations of Cicero's epistles. Besides reading Cicero's *Epistles*, the boy should gather likely phrases for letter writing from other authors, especially Terence. All such phrases should be entered, during the course of reading authors, in a notebook, divided into certain headings, easy of reference. Variation of expression should be sought. For this purpose Hoole recommends Erasmus' *De Copia Rerum et Verborum* and John Clarke's (*q.v.*) *Dux Oratorius*. Hoole's method of teaching boys letter writing is as follows. Ask a boy to whom he proposes to write his letter, and the subject of it. Then get the whole class to see who can write the most suitable letter in English, and how quickly. Amend the imperfections in each exercise. Take the best English letter, and let each boy give a Latin expression of his own, gathering from each boy words and phrases, and seek as much variety as possible. Put all those accepted down in writing, and then let the scholars write the Latin letter with the collected phrases before him for choice. One point of the exercise was to avoid barbarisms and anglicisms. Hoole advises that those who wish to write letters well should read good examples often, therefore boys in the upper forms should often read all Tully's *Epistles*, and sometimes should read from those of Pliny, Seneca, Erasmus, Lipsius, Manutius, Ascham, Politian, and "whatever they find in the school library, which should be very well furnished with epistolary books." In letter writing, Hoole claims that pupils should never "go about a new letter until they have finished what they had begun."

Letter writing, both in Latin and English, occupied a much more important place even in the eighteenth century than now, as an educational exercise. For the long news letters of our ancestors took the place of the modern newspaper, and accordingly practice in letter writing was a subject of practical importance in the schools, both for boys and girls. On account of familiarity with actual letter writing as a school exercise, early novels consisting of long interchanges of correspondence between the characters did not probably cause the sense of dullness with which they are apt to affect the modern reader.

D. G. Morhof in his *De Ratione Conscribendarum Epistolarum libellus* (Lübeck, 1716) gives a list of writers on the art and method of composing epistles. The list is surprisingly long, and includes the following: Demetrius Phalereus, Gregory Nazianzen, John Altenstaig, Raphael Brandolinus, Conrad Celtes, Ludovicus Vives, Erasmus Roterodamus, Melchior Junius, Lipsius, Johannes Voellus, Johannes Simonius, George Fabricius, Christopher Hegendorphinus, George Macropedius, John Mulinus, Simon Verepæus, Jodocus Jungmann, George Heunischius, J. H. Alsted, B. Keckermann, Henry Bebelius, Rocchiuse Piloreius, Thomas Sagittarius, Timplerus. "Whosoever desires more names," adds Morhof, "let him refer to the *Bibliotheca* of Conrad Gesner and George Drandius — not to mention other books." The most complete textbook on English letter writing is entitled: *The English Secretarie. — Wherein is contained a perfect method for the imiting of all manner of epistles and familiar letters, together with their diversities, enlarged by examples under their severall Tyes. In which is layd forth a Pathwaye, so apt, plainer and casier, to any learner's capacity, as like whereof hath not at any time heretofore bene delivered. Now first deiced and newly published by Angel Day* (1586). One of the best collections of English letters up to the date of its publication (1789) was in the series of *Elegant Extracts (Epistles)* by Vicesimus Knox, Headmaster of Tonbridge School, Kent (1778–1812), who wrote an interesting chapter on letter writing in his work on Education. **EPISTOLÆ VIRORUM OBSCURORUM.**

— A *jeu d'esprit* which is of considerable historical value as indicating the state of education in the universities in the early days of the humanistic movement, as well as forming one of the incidents which heralded the Reformation. Actually the *Letters of Obscure Men* were parodies of the *Letters of Illustrious Men (Clarorum Virorum Epistolæ)* addressed to Reuchlin and published to aid him before the Pope against the attacks of the Dominicans.

The *Epistolæ Virorum Obscurorum* purported to be letters addressed by admirers to Ortuinus Gratius, Professor of Arts at the University of Cologne, a center of reaction and obscurantism. They appeared in 1515, and there was considerable conjecture as to their authorship, Erasmus and Reuchlin himself being among those suggested. But the real authors were Hermann Busch, Crotius Rubianus, Wolfgang Angst, and to a later addition in 1519 Ulrich von Hutten contributed. The letters were published at Hagenau, but bore the address of the Aldine Press at Venice. The letters are written to the professor by young graduates in the worst possible Latin. No grammatical rules or idiom are observed, and the vocabulary is far from classical. The contents include accounts of the daily life of the correspondents, and express the narrowness of their intellectual views and activities as well as the dissoluteness of their lives. In educational history, they are chiefly important for the bitter opposition which is expressed against the introduction of humanistic studies and against the young "poets" who are beginning to assert themselves at the universities. The characters, which, however burlesque, were no doubt based on fact, are convicted of quibbling, straw splitting, ignorance of classics, and contempt for scholarship. According to Erasmus, the friars and monks took the work seriously as a tribute to their intellectual standing and achievements until a letter in the second volume shattered their illusions. The *Letters* were received with great acclamation by the whole intellectual world at the time, and if for the present century the humor which caused Erasmus to burst a pustule on his face with laughing is not so strongly apparent, the picture presented of the reactionary friars and opponents of humanism is as forceful as ever.

**EPITOME METHOD.** — The extensive study of a subject through the use of outlines, abstracts or summaries. This method is much used in the study of history, and is supplemental to the more intensive treatment of special periods, epochs, or movements.

See HISTORY, TEACHING OF; EPOCHAL METHOD; EXTENSIVE METHOD.

**EPOCHAL METHOD IN HISTORY.** — A study of history by periods or epochs. This intensive and more detailed method of procedure is frequently contrasted with the mode of teaching which employs outlines, abstracts, or epitomes. The two methods,

regarded as competitive, form the basis of a controversy current among teachers of history. A broader view would regard the two methods as supplementary. The use of outlines gives the broad setting and the continuity necessary to history study, but it lacks the thorough study of detail which characterizes the intensive study of history by periods. Because of the limit of time, the epochal treatment, on the contrary may leave the pupil quite ignorant of many periods and movements in history.

**EPSON COLLEGE.** — See GRAMMAR SCHOOLS, ENGLISH; COLLEGES, ENGLISH; PUBLIC SCHOOLS.

**EPWORTH UNIVERSITY, OKLAHOMA CITY, OKL.** — A coeducational institution established in 1904. Academic, collegiate, engineering, kindergarten training, commercial, pharmacy, medicine, law, music, oratory, painting courses are offered. A summer school of theology is maintained. The entrance requirements to the college are equivalent to about four years of high school work; certificates of affiliated high schools are accepted in place of examination. The degrees of A.B., B.S., Ph.B., are conferred on the completion of the appropriate courses. The faculty numbers eighty-four professors and instructors.

**EQUAL PAY.** — See TEACHERS, SALARY OF.

**EQUATION.** — An expression of equality between two quantities, as  $2 \text{ lb.} = 32 \text{ oz.}$ , or  $x + 7 = 15$ . In algebra (*q.v.*) the word is generally used to mean an expression of equality in which one or more unknown quantities enter. Thus in algebra, and particularly in the theory of equations, the expressions  $5 = 4 + 1$  and  $(a + b)^2 = a^2 + 2ab + b^2$  are not always called equations, but the former is spoken of as an equality and the latter as an identity. An identity is, therefore, an expression of equality that is true for any values of the letters involved, while an equation is an expression of equality that is true only for special values of a quantity considered as unknown. In elementary algebra this distinction was formerly made, and is often made at present, by speaking of  $x + 7 = 15$  as an equation of condition, the condition being that  $x$  shall equal 8. The usage is not uniform at present, but the question is not of enough importance to give any trouble in teaching.

Equations are classified in various ways. The classifications first met in teaching are as follows: As to degree, an equation is of the first degree if the terms containing the unknown quantities are all of the first degree, as in the case of  $x + 7 = 15$ , or of the two equations  $x + y = 10$ ,  $x - y = 6$ . An equation of the first

degree is also said to be linear, because in analytic geometry such an equation involving one or two unknowns is represented by a straight line. Such an equation is also called a simple equation. An equation of the second degree, or a quadratic equation, involves a term of the second degree, as in the case of  $x^2 - 7x + 10 = 0$ , or of the two equations  $xy = 12$ ,  $x^2 + y^2 = 25$ . An equation of the third degree, a cubic equation, involving one unknown quantity, has as its type form  $x^3 + a_1x^2 + a_2x + a_3 = 0$ , and, in general, one of the  $n$ th degree has as its type form  $x^n + a_1x^{n-1} + a_2x^{n-2} + \dots + a_n = 0$ .

Equations are integral or fractional according as the unknown quantity does not or does appear in the denominator of a fraction that has been reduced to lowest terms. Thus  $\frac{2}{3}x + 4 = 10$  is an integral equation, while  $\frac{2}{x} + 4 = 10$  is a fractional equation in  $x$ , as it now stands, although it may be looked upon as an integral equation in  $\frac{1}{x}$ , and although it may be reduced to an integral equation by multiplying both members by  $x$ .

If two or more equations have determinate values of the unknowns, they are said to be simultaneous. For example,  $x + y = 12$ ,  $x - y = 2$  are both true for  $x = 7$ ,  $y = 5$ . On the other hand,  $x + y = 12$  and  $x + y = 2$  are not simultaneous equations, but are said to be inconsistent.

If an equation contains a term in which a root of the unknown quantity is involved, it is called a radical equation. For example,  $\sqrt{x+4} = x - 2$  is a radical equation which may be reduced to a quadratic equation by squaring both members.

Equations are said to be equivalent if every root of each is a root of the other. For example,  $2x = 6$  and  $x = 3$  are equivalent equations; but  $x = 3$  and  $x^2 = 9$  are not equivalent, since the second has a root ( $x = -3$ ) that is not a root of the first. It is readily seen that the axioms of equality do not always lead to equivalent equations. If equals are multiplied by equals, the results are equal; but this does not mean that the results are in general equivalent to the original equations. For example, if  $3x = 9$ , it is true that  $3x^2 = 9x$ , but this second equation has a root ( $x = 0$ ) that is not a root of  $3x = 9$ .

Quadratic equations are classified as complete (affected) and incomplete (pure). A complete or affected quadratic has the type form  $a_0x^2 + a_1x + a_2 = 0$  where  $a$  is not zero. More simply expressed, the type is  $x^2 + a_1x + a_2 = 0$ . The English name for this type is affected quadratic. A pure quadratic equation is of the same type, where  $a_0$  does not equal zero but where  $a_1$  does equal zero. More simply, the type is  $x^2 + b = 0$ .

A single equation is determinate when it contains only one unknown quantity, and a system of equations is determinate when by elimination it can be reduced to a series of equations, involving the respective unknown quantities, and each containing only the one in question. Otherwise there is not, in general, a sufficient number of conditions to determine the value of the unknown quantities, and the system is then indeterminate. In general, if there are  $n$  unknowns and  $n - 1$  equations, the system is indeterminate, as in the case of  $x + y = 10$ , and of the system  $x + y + z = 10$ ,  $x + 2y + 3z = 25$ .

The ancient Egyptians solved equations of the first and second degree, and the Greeks, usually through the medium of geometry, did the same. (See ALGEBRA.) The greatest algebraist of the Greeks was Diophantus (*q.v.*). The cubic equation was first solved in the sixteenth century by the Italians, the first complete solution being due to Tartaglia (*q.v.*) and being first published by Cardan (*q.v.*) in his *Ars Magna* (1545). The quartic or biquadratic equation was first solved by Ferrari (1522-1565). The general quintic (fifth degree) equation does not admit of solution by the use of algebraic functions. It can be reduced to the form  $x^5 + ax + b = 0$ , and criteria have been developed for telling under what circumstances such an equation is soluble. That the general quintic could not be solved by algebraic methods was completely proved by Abel early in the nineteenth century.

**ERASMUS** (1466-1536). — The best known man of letters of the Northern Renaissance was the son of Gerard of Gouda and Margaret, the daughter of a physician of Zevenberge, whose union was unsupported by the Church. His name, as fully written on the title pages of his works, is Desiderius Erasmus Roterodamus, Desiderius being the Latin equivalent of the Greek Erasmus, and the form Erasmus being the actual name bestowed on the child by Gerard. Erasmus, at nine years of age, entered the famous school of the Church of St. Lebuin at Deventer, under the headmaster Hegius (*q.v.*) and assistant Sintheim (*q.v.*); but

Erasmus in later years writes of the school: "Deventer was a school still in the age of barbarism." In 1480 Erasmus proceeded to the School of the Collationary Brothers (see BRETHREN OF THE COMMON LIFE) at Bois-le-Duc for two years. In 1483 he entered on his novitiate at an Augustinian monastery at Stein near Gouda, where he lived for ten years, and in 1492 he became a priest. In 1493 he was sent by the Bishop of Cambrai to the University of Paris to study theology. There is no doubt that both in the monastery and in the university, Erasmus' chief study was the classics. At Paris he taught Latin, and in 1495 came into contact with English students in Paris, there meeting his future patron, Lord Mountjoy. At this time he wrote his book *De Conscribendis Epistolis*, letter writing being one of the recognized methods of instruction of the time in teaching Latin. In 1499 Erasmus came to England with Lord Mountjoy, and became acquainted with Colet and More. He returned to Paris before the end of the year. In 1502 he went to Louvain, but was back in Paris in 1505. In 1506 he went to Italy, and in 1507 Erasmus joined Aldus at Venice and assisted him in editing the classics. In 1510 Erasmus became Lady Margaret Professor of Divinity, and taught some Greek at Cambridge, where he remained till 1514. From 1514 to 1517 he was traveling. In 1517 the *Collegium Trilingue* was established at Louvain, and Erasmus was consulted as to its organization. In 1519 he settled at Louvain, and here met Juan Luis Vives (*q.v.*). In 1522 he moved to Basel, and spent the rest of his life between Basel and Freiburg in Breisgau. He died in 1536 at Basel. Erasmus was thus a cosmopolitan. But it has been doubted whether he spoke any other modern language than his native Dutch, and it is certain that he usually spoke and wrote in Latin. His editorial services in connection with classical writers included work on Æsop, Ambrose, Aristotle, Arnobius, Athanasius, Augustine, Basil, Cato, Cicero's *De Amicitia*, *De Senectute*, and *Tusculanæ, Quæstiones*, Cyprian, Demosthenes, Euripides' *Hecuba* and *Iphigenia*, Jerome and Quintus Curtius. Nor is such a list complete. Still more significant is Erasmus' preparation of what was the *editio princeps* of the Greek text with a Latin translation of the New Testament, called by Erasmus the *Novum Instrumentum*, published at Basel in 1516, though it is probable most of the work in it was done by Erasmus at Cambridge in England. In the preface, Erasmus claims substantially that the Latin Vulgate edition of the Bible must be subjected to criticism the same as the classical authors. Further, Erasmus expresses his wishes that all — "even the weakest woman" — should read the Gospel for themselves. He is thus the first exponent of modern Biblical criticism. Politically, he claims notice by his tract *Querela Pacis*, with its noble protest against war.

Erasmus was a warm friend of Dean Colet and his school of St. Paul, refounded about 1510. He wrote for it some *Carmina*, some verses on the school motto, *Disce aut Discede*, and a *Concio de Puero Jesu*. He also wrote the school textbook *De Copia Verborum et Rerum* (1511). This is a storehouse of rhetorical phrases, which could serve as the very basis for free, ready, and correct Latin composition. *Copia* is the supply of words, phrases, idioms, which gives variability so as to be comprehensive, and with it style so as to leave nothing out in the way of matter, and yet to keep the limit of economy of words. The *Copia* is said to have gone through nearly sixty editions in Erasmus' lifetime, and certainly was not less popular for a century afterwards. The *De Copia* was prescribed by statute for St. Paul's School (1518), though used there before. In 1545-1547 it was used at Saffron Walden Grammar School. It was prescribed in the Statutes of Bury St. Edmunds (? 1550), Retford (1552), Bangor (1568), and in many other English schools. The other great works which may be described as educational textbooks written by Erasmus were the *Adagia* (1st ed., 1500) and the *Apophthegmata* (1532). The *Adagia* in its first form gave about eight hundred proverbs; in its later form five times as many. Proverbs were given in Greek as well as Latin, and the book could thus be used as a Greek textbook. In fact, as Mr. Drummond has said, "besides to a great extent serving the purpose of a dictionary and a grammar, it is a commonplace book, a journal, and a book of travels all in one." The *Apophthegmata*, or *Sayings of the Ancients*, gives little stories of ancient writers (Socrates, Aristippus, Diogenes, Cicero, Demosthenes are drawn upon), with usually some moral deductions giving scope to Erasmus to introduce all kinds of material of his own. In 1519, Erasmus published the *Colloquies*, one of the most widely used school-books of the sixteenth and seventeenth centuries throughout Europe. The University of Paris forbade the use of the book in 1528. It was condemned in 1564 at the Council of Trent. Naturally, in Protestant countries, it was spread broadcast on account of its attacks on monks, abuses, and superstitions. It was required by statute to be taught in many English grammar schools. The subjects are most varied, and are treated by the dialogue method, and, of course, written in Latin. (See COLLOQUIES.)

But, besides positive work for education, Erasmus was particularly strong, a modern Lucian, in his satires on what he considered corrupt and evil. The *Moriæ Encomium* (*Praise of Folly*) (1509) holds up to ironical praise the whole race of monks, scholastic divines, grammarians, and by ridiculing the old order of learning, opened the way for the new ideas of the Renaissance. While it cannot be said that the educational opinions of Erasmus are con-

fined to any one book or number of books, the following among his works deal more specifically with education: the *Enchiridion Militis Christiani* (1501); *De Ratione Studii* (1511); *Institutio Christiani Hominis* (1516), a manual used in St. Paul's School; *Institutio Christiani Principis* (1516); *De Pueris statim ac liberaliter instituendis* (1529). The *De Ratione Studii*, or *On the Right Method of Study* sets forth a plea for the study of language, *i.e.* Greek and Latin, which are complementary and contain "the whole of attainable knowledge"; more attention should be paid to style and content rather than grammar for its own sake. Erasmus then proceeds to suggest methods of teaching in which the capacity of the pupil should be considered and the awakening of intelligence and critical insight should be aimed at. In the *De Pueris statim ac liberaliter instituendis* (*That pupils should straightway from their earliest years be trained in virtue and sound learning*), a treatise addressed to William of Cleves, Erasmus points out the importance of the proper selection of a teacher, and recommends that parents should take a personal interest in the education of their children, for they are begotten to the commonwealth and to God. Education must begin early, and depends on nature, practice, and training; the liberal arts are the handmaidens of conduct; above all love and sympathy for the child, not fear and harshness, should be the stimuli employed. It is in this essay that Erasmus attacks the monastic schools, and insists that it is the duty of State and Church to see that a supply of properly qualified teachers is maintained. The work is one of the best expressions of the humanistic ideal of education by one of its most brilliant representatives who was qualified by experience to speak with some authority.

**ERATOSTHENES** (275-194 B.C.). — A prominent Greek scholar of the first Alexan-

drian school. He was a personal friend of Archimedes, and was librarian of the university at Alexandria. He is chiefly known for his work in astronomy and geodesy, determining the obliquity of the ecliptic as  $23^{\circ} 51' 20''$ . He also calculated the radius of the earth as the equivalent of about 4600 miles, and the length of a degree as about seventy-nine miles. We are not certain as to the unit of measure used by him, and it is possible that his results were even closer than these. In the theory of numbers he is known for his "sieve," a scheme for sifting out the prime numbers. This plan was frequently given in arithmetics until a generation or so ago. Eratosthenes was also a poet and a general all-round savant. Afflicted by ophthalmia, he committed suicide in 194 B.C.

**ERFURT, UNIVERSITY OF.** — The University of Erfurt in Thuringia was established as early as 1392, being the third university to be established within the confines of the present German Empire, Heidelberg having been founded six, and Cologne four years earlier. It attained considerable prominence as a seat of humanism, but suffered greatly during the wars of the Reformation, and was finally disbanded in 1816.

**ERGOGRAPH.** — An apparatus for recording the amount of work which an individual can perform under given conditions. The apparatus is generally so constructed as to isolate a small group of muscles and record the number and extent of the contractions which these muscles are capable of making before reaching that state of fatigue where contraction becomes impossible. The original form of the ergograph required the muscles to raise a weight. A later form utilizes a spring instead of weights. The curves derived through the use of the ergograph have been commonly used in discussions of fatigue (*q.v.*).

**ERIUGENA, JOHN SCOTUS.** — An Irish teacher, theologian, philosopher, and poet, who lived in the ninth century. There is now no doubt among scholars as to the birthplace of Eriugena, or, to use the name by which he was known to his contemporaries, John the Scot. He was born in Ireland about the year 820, and presumably was educated in the schools of his native land. About the year 847 he appeared at the court of Charles the Bald, and, as is evident from contemporary references, was received into royal favor and placed at the head of the palace school. At the invitation

of his royal patron, he translated into Latin the works of Pseudo-Dionysius. This task had a double effect on his career; by bringing him into prominence in the world of letters, it was the occasion of his entering into the controversy raging around Gottschalk's predestinarian doctrine and at the same time it opened up to him a new philosophical world, that of Neo-Platonism. As a controversialist he wrote the work *De Predestinatione*, and as a Neo-Platonic philosopher he composed the treatise *De Divisione Naturæ*. Besides these writings he left a number of commentaries and glosses, the most important of which are the *Commentary* on Marcellinus Capella (*q.v.*) and the glosses on the *Opuscula* of Boethius (*q.v.*). From the last, which were published by Dr. Rand in 1906 (*Johannes Scottus*, Munich, 1906) it appears that he was still alive and in France as late as 867. The date and place of his death are unknown. The legend which tells of his having gone to Oxford at the invitation of Alfred the Great, and the equally legendary account of his death and burial at Malmesbury, are devoid of historical foundation. The works of John the Scot, including his translations, are published by Migne in Vol. CXXII of the *Patrologia Latina*.

Besides being a theologian and philosopher, John the Scot was a teacher and a copyist of manuscripts. As a speculative thinker he ranks very high, his preëminence being all the more noteworthy when one recalls how totally the ninth century was lacking in the spirit of constructive or any other kind of original effort. As a teacher he was one of the group of Irishmen who gathered at Laon and engaged in the study of dialectic, theology, and Greek. The specimens of their work which have survived the wreck of time should not be judged by the standards of modern philology. Considering the age from which they come, they are interesting, and not altogether valueless in the history of classical learning. As a copyist, John the Scot transcribed and glossed a number of school texts, some of which have come down to us in the original autograph. Such, at least, is the opinion of the distinguished palæographer Traube. The mystic elements in John's philosophy and theology had comparatively little influence on his contemporaries. It was not until the first decades of the thirteenth century that the bearing of his pantheistic ideas was recognized and his doctrines formally condemned. His predestinarian doctrines had been condemned during his lifetime at the local councils of Valence (855) and Langres (859). W. T.

**ERK, LUDWIG** (1807-1883).—A prominent German composer, born in Wetzlar. In 1826 he received an appointment at the Teachers' Seminary at Mörs, which at that time was under the direction of Diesterweg (*q.v.*). When Diesterweg was called to Berlin, Erk followed him in 1835 as teacher of music of the City Training School, where he remained for the rest of his life. Erk's influence on German schools was especially exerted in the direction of fostering the beautiful and simple German folk songs, and for this he deserves great credit. He published a number of song collections, which became very popular; among them is his *Deutsche Volkslieder* (*German Folk Songs*), Berlin, 1832-1845. F. M.

**ERLANGEN, THE ROYAL BAVARIAN FREDERICK-ALEXANDER UNIVERSITY OF.**—An institution founded in the year

1745 by the union of an academy, established at Bayreuth in 1742, and a *Ritterakademie*, established at Erlangen in 1699 by Baron Adam Gros von Trockau. The new university possessed the four traditional faculties of theology, law, medicine, and philosophy from the start, but it led a rather precarious existence until given a new lease of life by Margrave Christian Frederick Carl Alexander of Ansbach, who entered upon his activity in 1769, and whose name has been preserved in the designation of the university. The theological faculty was Protestant, the town having attracted a considerable number of French Protestants who had been exiled by the revocation of the Edict of Nantes. In 1806 the principalities of Ansbach and Bayreuth, which had been absorbed by Prussia in 1792, were occupied by the French, and although the university was not discontinued, its income was seriously diminished, and it suffered much hardship. Four years later the principality of Bayreuth became Bavarian, and a new era of progress was ushered in, which was reflected in the better provision made for medical and other scientific institutes and laboratories. The number of students in these subjects increased rapidly during the early eighties, and as a result a number of well-equipped buildings have been erected during the past twenty-five years in order to meet the new demands. Until 1850, the large majority of the student body was enrolled in the faculties of theology and law, but at the present day philosophy and medicine are in the lead, the number of students in the pure science division of the faculty of philosophy particularly showing a considerable gain of late. During the winter semester 1909-1910 there were 1187 students (forty-one women) in attendance, including sixty-four auditors (twenty-two women), the matriculated students being distributed as follows: theology

139, law 247, medicine 294, and philosophy 443. It is thus one of the smallest of the German universities, exceeding only Greifswald and Rostock in point of enrollment. The library contains almost 250,000 volumes and over 2000 Mss. Among renowned teachers may be mentioned Ebrard in theology, Sehelling in philosophy, the poet Friedrich Rückert in Oriental languages, and von Raumer in German philology.

**ERNESTI, JOHANN AUGUST** (1707-1781). — A distinguished German theologian, philologist, and schoolman, one of the leaders of the "New Humanism," was born in Tennstedt, Thuringia, and received his education at Schulpforta and the universities of Wittenberg and Leipzig. In 1731 he became the colleague of Gesner (*q.v.*) at the Thomasschule in Leipzig, and three years later, when Gesner was called to Göttingen, Ernesti succeeded him, and, for a quarter of a century, remained at the head of the school. He also delivered lectures at the university, where, in 1742, he received the regular appointment as Professor of Eloquence. In addition, he accepted the chair of theology in the university (1759), but resigned his position at the Thomasschule. His influence, however, on the higher schools of Saxony, and through them on those of other German states, remained very great. The *Regulations for the Saxon Schools* which he wrote in 1773 were in force for nearly three quarters of a century. He condemned the old methods of teaching the classics, by which it was attempted to give the student merely the ability to write Latin and to imitate the style of Cicero, and insisted on the reading of the ancient authors for the sake of their content and for the cultivation of literary taste and understanding. He laid great emphasis on the teaching of the mother tongue and the reading of the best works of the national literature, as well as on modern foreign languages, history and geography, philosophy and mathematics, including geometry, astronomy, mechanics, and architecture.

About the middle of the eighteenth century classical studies were at a very low ebb in Germany. Through the influence of Gesner and Ernesti and their disciples, however, a new impulse was given to classical learning, and that enthusiasm for antiquity was aroused which is later found in the works of Goethe and Schiller, and which determined the character of the German gymnasium down to the second half of the nineteenth century. Among Ernesti's works the one most used in the schools was his *Initia*

*Doctrinae Solidioris*, 1755, which contains the elements of mathematics, psychology, natural theology, logic, jurisprudence, ethics, politics, and physics, with astronomy and physiology. He published also a number of editions of Greek and Latin authors, besides some theological writings and over a hundred smaller essays and dissertations. Many of these have been collected in his *Opuscula Oratoria* (1762) and *Opuscula Philologica et Critica* (1776).

**ERNST I, THE PIOUS** (1601-1675). — Duke of Saxe-Gotha and Altenburg, the "Pedagogue among Princes," was born in Altenburg, where he received a very careful education under the direction of his mother, Dorothea Maria of Anhalt. Being an ardent adherent of Protestantism, he allied himself in the Thirty Years' War with the Swedes, and fought valiantly, first under Gustavus Adolphus, then under his own brother, the famous Bernhard of Weimar, in the battles of the Lech, Nuremberg, Lützen, and Nordlingen. In 1635 he signed the Peace of Prague, and henceforth he devoted all his efforts to the government of his duchy, the people of which had, in consequence of the terrible war, sunk into a very sad material and moral condition. Through excellent laws and a wise and economic administration, he succeeded in making Gotha one of the most prosperous parts of Germany. His educational reforms were of such a fundamental character that he may be regarded as the real founder of the present common school system of Germany. With the help of Reyher (*q.v.*), a disciple of Ratke and Comenius, he worked out a comprehensive set of school regulations known as the *Schulmethodus* (1642). This code, a pedagogic masterpiece of the seventeenth century, provided for compulsory school attendance and regulated in detail the grading of schools, the courses of study, and the methods of instruction. In addition, the duke caused a number of textbooks to be written by Reyher, and distributed gratis to school children. He raised the salaries of teachers, and instituted a pension fund for their widows and orphans. During his thirty-five years' reign, the intellectual level of his people was raised to such a degree that it used to be said that "Duke Ernst's peasants were better educated than noblemen are anywhere else."

**ERROR OF OBSERVATION.** — Common sense usually assumes that there is no evidence so direct, so accurate, and hence so convincing as that given immediately by the senses. However, a comparison of the observations of different persons upon the same object, or of different observations of the same person upon an object which cannot be supposed to have changed in the interim, reveals the fact that the evidence of the senses is full of contradictions, and consequently of errors. The Greek philosophers were for the most part so convinced of this view that they held the senses to yield only error and illusion, and sought in pure reason alone that truth which is free from contradiction. Modern thought, however, has attempted to analyze the causes of errors of observation, and to devise methods by which they may be minimized or eliminated.

In general, the classification and explanation of such errors is a matter of psychology. We do not observe accurately, either because the sense organs do not operate in a perfect way, or because the mental interpretations of sensation are incorrect. The errors due to the defects in our sense organs are various. In general, the sort of sensation that we get depends upon our sense organs, rather than upon the stimulus. A given stimulus will give rise to the sensation peculiar to the sense organ that it affects. If pressure were to affect the retina, we should get light sensation. It follows that if we judge the stimulus to be that which commonly arouses a given sensation, we may be in error. Moreover, certain qualitative, quantitative, and temporal differences and relations our senses may not be able to take account of. For many types of stimulus we have no special sense. Such differences are either lost or rendered imperfectly in terms of other differences that can be perceived. Only the grosser differences in intensity among

stimuli can be perceived. Duration and precedence in time are very inaccurately estimated or determined where the amounts are small. Many times a sense organ is stimulated pathologically, as when the ears ring from a cold; or by reaction from other sensations, as in the case of negative after-images of sight, or by association with sensations from other senses, synæsthesia, well illustrated in so-called colored hearing. The estimate of magnitude is largely dependent on kinesthetic sensations, and many illusions of form, size, etc., are due to the peculiarities in the movements by which the objects are exploited by the sense organs. The mental attitude has much to do with the character of the sensations that we get. Attention determines the clearness of the sensation, and may result in an apparent modification of it. If two objects of the same shape and weight, but of different size, are lifted, the larger one will be felt to be the lighter. We are surprised that it should be so light, and the stress of attention produces the illusion of extreme lightness. Of two contemporaneous incidents, that upon which the attention is fixed is apt to be judged as coming first.

In the case of illusions of mental interpretation, the two types distinguished by Professor James may be noted, — illusions of habit, or apperception, and illusions of expectation, or preperception. Illusions of habit are cases where the habitual interpretation which is given to a sensation happens to be the wrong one. They may be illustrated by Aristotle's illusion of touch. An object placed between crossed fingers appears double, since the surfaces affected could not in the ordinary position of the fingers be touched by the same object at the same time. An illusion of expectation is found in proofreaders' oversights. They see misspelled words, for example, as spelled correctly, because the correct spelling is in the mind. The extreme type of such an illusion is in the hallucination, where apparent sense perceptions are constructed almost, if not quite wholly, out of imagination. Practically all illusions will on analysis reveal elements that will allow of their being classified as illusions of habit or of expectation.

The accuracy of observation increases with training, and so with age. Uncultivated persons show on the whole more imperfections in their observations than do those who have had better advantages. Observations reported after an interval of time are liable to the distortions of an imperfect memory. Suggestions of all sorts may affect such reports, and even the original observation may be affected by suggestion. The suggestion of a lawyer or of the situation may warp the memory of a witness without his realizing it. Children can easily be subjected to suggestions. While, on the one hand, they possess a certain "innocence" of sense, since their minds are not

so full of interpretations to apply fallaciously to sensations as are those of adults, on the other, they lack a critical sense by which observations can be rendered exact. Children may easily be persuaded that they smell odors that do not exist. Indeed, such illusions can readily be suggested to adults, especially if their emotions are stirred.

Scientific men, recognizing the liability to errors of observation, have endeavored to take account of them mathematically, so that results might be subject to correction corresponding to known or probable errors. In some cases it is found that observation makes a certain error invariably. Such an inaccuracy is called a constant error. The astronomer's "personal equation" is an example of this. If one is attempting to note the time of an astronomical event, it will seem to come earlier when his attention is fixed more on the clock, and later when he is thinking more of the event itself. This tendency in the individual may be experimentally measured and his observations corrected. Where many observations are made of the same or similar phenomena, and it is noted that there are many differences which can be ranged about a median (see STATISTICAL METHOD), we may suppose that the errors are due to a variety of causes, and that they are distributed as by chance, some in one direction, some in another. In such cases the probable error can be calculated. The chances that the correct observation falls within certain limits are thus stated mathematically. The probable error is a most important factor in determining the reliability of statistical results. E. N. H.

**ETHICAL CULTURE SCHOOL, NEW YORK.** — An institution which provides instruction from the kindergarten through the high school and maintains a department for the train-

ing of kindergarten teachers. It is an outgrowth of the first free kindergarten established in New York (1878) by Felix Adler, the founder of the Ethical Culture Society (1876). The aim of this Society, which now is organized in many cities in the United States, England, Germany, Austria, and Switzerland, is to seek what is good and to promote the moral development of the individual and society. The school was established as a practical experiment to base education on the principles of the Ethical Culture Society. It aims to develop persons competent to readjust this environment in accordance with moral ideals and to impart an enthusiasm for progress which centers in moral relations and the diminution of the evils of the world. Hence emphasis is laid in all departments of the school on direct ethical instruction, as well as all possible indirect moral influences based on social relations between the different classes, for the school tolerates no distinction of race, creed, or social status. The freedom enjoyed by the school has been employed in promoting experiments in the teaching of the different school subjects, especially in English (see FESTIVALS, SCHOOL), in manual arts, in which the school was a pioneer, and in history. Literature, history, and manual arts are closely related with the ethical instruction in promoting the essentially moral aim of the school. A healthy democratic spirit, sympathy between different classes, creeds, and vocations, an appreciation of the evolutionary progress of the world, and a consciousness of the unity of all human beings and human activities are the desired ends of the Ethical Culture School.

**ETHICS AND EDUCATION.** — **Historical and Theoretical Relation of.** — Since good and evil are incident to life, and there are right and wrong ways of attaining good and avoiding evil, there is a natural incentive to morals. It would appear, therefore, that ethics — which is the attempt to give our interest in what is good and bad, right and wrong, the proportions of a science — would be chiefly concerned with the classification of natural goods and the discovery of the most efficient means of securing and disseminating them. But its problems have seldom been so naturally and so simply conceived. Instead of a primary interest in the classification of goods, ethical inquiry has shown much greater interest in such problems as the nature of the good, the relation of the

good to the useful, the pleasant, and the desirable, and whether there is one good or many goods. And instead of a primary interest in discovering the most efficient means by which the goods of life may be secured and disseminated, it has shown much greater interest in inquiring about the nature of obligation, the foundation of rights and duties, the extent of responsibility, and the freedom of the will. In other words, there has generally been a "moral" coloring to human reflection on the pursuit of the good, a sense, that is, that men confronted by the consideration of good and right have other and deeper problems than that of means to ends. Thus Plato could picture the perfectly unjust man as one who none the less might have in all quarters the reputation of justice; and Kant could exclaim, "The sight of a being who is not adorned with a single feature of a pure and good will enjoying unbroken prosperity can never give pleasure to an impartial, rational spectator." These illustrations may give one the feeling of what is meant by "moral," a feeling which it is easier to appreciate than to define. An adequate understanding of it can be had only from a study of the general development of moral ideas. This is a large task, and can be treated here only in a summary fashion.

It is customary to claim that ethics first attained something like the dignity of an independent science with the Sophists of ancient Greece (*q.v.*), that is, about the fifth century B.C. The claim may be allowed, provided we remember that it is significant only in view of that particular course of civilization which Europeans and their descendants are wont to regard as the main line of the world's progress. But the beginnings of the science of ethics were naturally not the beginnings of morality. The terms "ethics" and "moral," having, as they do, the primary meaning of the customary and habitual, indicate very clearly that moral philosophy began in reflection on the established customs and habits of the society which produced it. Indeed, if it is usual to begin the history of the science of ethics with the Greeks, it is also usual to begin the history of morals with the rites and ceremonies of primitive peoples, their clan and group customs, their habits of living. It is characteristic of these customs and habits that they are thought to be helpful in promoting the general well-being of the community, and it is apparent that they gradually grew up as organized methods of controlling the forces of nature and the conduct of individuals. Yet it is also apparent that primitive society does not justify them on utilitarian grounds. They have that peculiar sanctity which, as already noted, is called moral, a sanctity which makes them binding even when they are not serviceable, and which steadily opposes change and innovation. Thus in the most primitive societies with which anthropology has made us

familiar, we find that individuals are expected to make their conduct conform to customs long established and carefully guarded, and that lack of conformity is severely dealt with. Primitive morals consist thus of organized practices which confine the conduct of individuals within restricted limits, not because these practices have proved to be really serviceable, but because they are felt to be authoritative and obligatory. They determine the training of the young and shape the ideals and practices of education in its beginnings.

See PRIMITIVE SOCIETY, EDUCATION IN.

How the practices which constitute primitive morals get that peculiar sanction which is strong enough to outweigh for generations and even centuries the failure to meet the test of genuine serviceableness, is an inquiry of considerable interest and of remarkable difficulty. It is important to note that they have this sanction long before any one thinks of questioning it or discovering reasons for it. As a consequence, it turns out that the reasons savages give for their customs and habits are far from reliable. Even with peoples of considerable civilization, it is usual to find that their established practices are referred back to some early legislator whose personality is largely mythical, or to the revelation of some divinity. All of this goes to show that men have often been more interested in making morals authoritative than in discovering exactly why moral practices are performed. Perhaps we should say, in view of the facts at our command, that these practices get their sanction originally because of their congruity with what we may call primitive imagination. They fitted well into the general picture of things which men rather spontaneously formed, and thus became intimately bound up with their outlook upon life and the world. If this is so, it is perhaps not difficult to understand why the reasons given for their performance after they have become established are so inadequate as explanations of their origin.

It is to be noted also that morals undergo many transformations, and exhibit great variety, quite independent of any marked reflection upon them. Historians have traced with considerable success these variations, and found explanations of them in physical, economic, and social conditions. It is natural to suppose that as these conditions change, the customs and habits of men will change with them. Utility, too, must evidently be an important factor in moral development. For while practices long continue the utility of which is questionable, it is inevitable that these practices tend to break down in proportion as they fail of genuine serviceableness. Thus we may recognize a natural evolution of morals, to a large extent independent of reflective ethical inquiry.

Now, while it would be unwarrantable to claim that there was no such inquiry before

the Sophists, or that it was not an important factor in moral development, the general considerations we have noted do, none the less, afford an approximately accurate setting for the reflections of the Sophists. They met a body of established practices sanctified by authority and tradition, marked by many indications of a long history, and of derivation from many contributing sources. The situation which they thus faced they put in question. The incentives to their procedure are doubtless to be found in the social movements of the time; but our concern is with the procedure itself rather than with its causes. We may note, however, that amid all the moral practices of the Greeks which concern the relations of individuals to one another and to society at large, the rights of property, the relation of the sexes,—that general domain which we cover by the terms "rights," "duties," "obligations,"—there had grown up the conception of individual virtue or excellence. The Greek imagination had formed a picture of the kind of man it was worth while to be. This picture had found its way into story and drama, but it had also been drawn in terms of moral precepts. The "nothing in excess" and "know thyself," which Plato tells us had been dedicated to Apollo at Delphi as the first-fruits of wisdom, express an idea of balance and intelligence. Wise men like Thales, Solon, and Bias held a place in the popular mind on account of their practical wisdom and their apposite sayings. These conceptions of human excellence do not, however, seem to have advanced much beyond their exhibition in individual character or in proverbial utterance. Even Democritus (460-360 B.C.), who was one of the most conspicuous of Greek thinkers, and who is credited with the production of a work on ethics, seems to have been contented with wise sayings instead of acute analysis. His "golden sayings" are golden, but they do not form an inquiry.

In striking contrast to Democritus stands his townsman and contemporary, the Sophist Protagoras (480-411 B.C.). He too had a great saying, well known to history: "Man is the measure of all things, of things that are, that they are, and of things that are not, that they are not." That saying is an ethical reflection which is typical of the sophistical movement in its prime. It attempts to cut morals off at once from authority and tradition, and to found human conduct directly upon human nature and man's primary interest in his success and well-being. According to the Sophists, the rules with which men's conduct may be reasonably expected to conform are the rules which are determined by his nature and needs. So the Sophists *taught*. Their great business was education, to free men's minds by a thorough acquaintance with human society and the world in order that human conduct might be freely directed toward the attainable and satisfactory. It is no wonder that they

were regarded as the destroyers of tradition, or that they wrought a revolution in education. Since they regarded virtue as the decent equipment of men for life, they made education the indispensable adjunct of morals, and at the same time determined its content and methods in view of the new moral demand. Ethics and education, so far as they indicated intellectual interests, were practically identical.

The relation of Socrates (468-399) to this general movement is ambiguous. He was one with the Sophists in his contention that virtue can be taught, that knowledge and morality go hand in hand, that enlightenment of mind is prerequisite to right action. But history credits him with a violent opposition to the Sophists. It looks to us now as if that opposition may have been rooted more in social and political considerations than in any genuine difference in aim or method. Yet there seems to have marked the teaching of Socrates a profound sense of the ultimate unchangeableness of whatever can be called good and bad, right and wrong, which the Sophists lacked. He seems to have created a passion for discussion and an engaging search for that "real truth inside man" which would both illuminate conduct and satisfy the mind. This he did with an ironic modesty which made that truth forever just beyond one's reach, and yet was so unshakably backed up by a firm belief in that truth's reality that faith instead of skepticism was the result. That justice, temperance, courage, the good, are not things to be changed as suits the opportunity, but thoroughly genuine and changeless, eluding our definitions, perhaps, yet unalterable possessions of the soul—such seems to have been the faith of Greece's greatest talker.

Plato (427-347) had this same faith by temperament, enriched it through companionship with Socrates, and transformed it by his own genius into one of the perduring philosophies of history. If life is to attain the dignity of the best, be the kind of life it ought, it must, according to Plato, involve a vision of the good and express that vision in a realized social order. But vision and expression interplay, for the good is seen not through isolated self-analysis of the soul, but through the perfectibility of social relations which men's natural admiration of the good discloses. There is a kind of analogy between the individual and society, so that the Greek ideal of intelligence and balance in a man is but a reading in smaller letters—the figure is Plato's—of intelligence and balance in the State. Furthermore, intelligence and balance are conceived to be ideals not only of conduct, but also of appreciation, so that the good becomes the concept of every excellence, the beautiful as well as the useful and the true. Plato asks us thus to contemplate a vision of beauty as well as an ideal of conduct and a goal of thought. But the essential thing is that this contemplation must be

worked out in social terms, and, when worked out, is seen to disclose the enduring pattern of things which attracts by its own excellence and creates by its own power. Particulars of conduct, things like justice and temperance, which we call the virtues, appeared thus to Plato to be dependent on a whole of excellence, to be its manifold instances, or some relation interwoven with them. One could not be genuinely virtuous in some single direction, but rather more or less virtuous as a whole and as a member of a society which as a whole is more or less virtuous. The good is one. Seldom has history revealed a finer faith in its reality and in its possibilities.

The practical problem set by the philosophy of Plato was the organizing of society in the interest of the ideal it discloses, and this he conceived to be primarily the problem of education. The details of his system we still read with surprise at their boldness, their novelty, and their foresight. They are everywhere joined to an insistent demand, which is both the fundamental characteristic of the Platonic scheme of education and a natural result of his ethical attitude. That demand is that education should aim at individual disinterestedness. So Plato valued more highly the studies we call abstract and speculative than those we call concrete and useful. The latter, he believed, fix attention on the immediately practical and the isolated, and thus, by fostering the desire for individual success, promote the impulses which lead to social disorganization. The former, however, by fixing attention on the impersonal and the general, tend to minimize the purely individual ambitions and desires, give breadth of view, and thus make possible a clearer vision of the social good. Philosophers were to head his State, solely because they are trained to pass disinterested and impersonal judgments upon the affairs of life. To believe that the good as realizable is a social ideal, and to teach with an eye primarily to individual efficiency or success, involved for Plato an insuperable contradiction. That is why the peculiarity of his educational problem is a natural result of his ethical attitude.

The ethics of Plato constitute an important document in the history of education. Wherever we find the insistence that education should equip youth for life by making them broadly disinterested rather than narrowly efficient, by teaching them subjects which make for largeness of mind rather than for practical success, by fixing the attention on something which cannot be measured by worldly accomplishment, there we find the spirit of Plato either directly exerted or arising from some fresh contemplation of social ideals. It has been a dominant spirit in education for centuries, shaping ideals and methods, and begetting that idea of education which we call liberal. (See HUMANISM; LIBERAL EDUCATION.)

Aristotle (384-322) keeps his thinking true to the general conception that the central problem of ethics is to provide an ideal for conduct. But he individualizes the ideal, laying stress, as did Socrates and the Sophists, upon personal attainments. Yet he does not conceive the best possible life as independent of social relations. It must be worked out, if it is to be attained, in the best possible State, but it is primarily a matter of individual perfection rather than of the perfection of society. While Plato could maintain that the individual happiness of citizens is subordinate to the perfection of the State, Aristotle held that the State is at best but an instrument in aid of individual well-being. It is one of the goods of life which, like maturity, health, friends, and property, minister to men's larger capabilities. He thus conceived ethics to be a branch of politics, not because the State comes rationally first as setting an ideal, but naturally first as the environment of human relations and the domain of human activities. Moreover, the ideal is not with him the Platonic pattern of goodness that attracts by its excellence and creates by its power; it is rather the free exercise of the function or activity which is peculiarly characteristic of man. All things, thinks Aristotle, have their characteristic activities which largely distinguish what they are, and the free exercise of which constitutes the good at which all things aim. The best life for men involves, therefore, the exercise of all their natural activities, but particularly the exercise of that activity by which men are peculiarly distinguished. And this is reason. Now the ideal which reason sets is twofold. It involves the virtuous control of conduct and the free exercise of reflection. Accordingly the ethics of Aristotle comprises an examination of the virtues, those types of excellence which make the admirable man, and also an emphasis on intellectual exercise pursued in its own interest for the self-sustaining joy of it. Thus the perfect man must be not only a citizen possessed of mature powers, abundant wealth, and friends, admirable for his justice, high-mindedness, temperance, and generosity; he must also be reflective, letting his mind play freely about the concerns of life and the constitution of nature in order that he may attain the supreme excellence of disinterested intelligence. In a sense this is Plato transformed, a faith in an enduring pattern of goodness translated into terms of human psychology and natural science, and presented as a goal of activity rather than as an insight into abiding realities.

This suggested contrast is illustrated in Aristotle's treatment of the virtues. With him they are not partial though related manifestations of a good essentially one and eternal, they are rather organized and controlled tendencies to action in those critical situations where the possibilities of behavior are contrasted and opposite. Thus a man is courageous when he has acquired

the settled habit of reacting to danger with his natural tendencies to flight or rashness controlled. He is, as it were, a "mean" between the cowardly and the headstrong. Other virtues are similarly construed. Here again we have the familiar Greek emphasis on balance and intelligence, but it is defined now in terms of the formation of habits. And if the virtues are to be unified, they can become so only as the individual attains a unified control of his habitual reactions in the face of the varied crises of conduct. If this unified control is to be attained, he must carry his conduct up into the domain of reflection, where the bearing of things can be seen and appreciated. "Anybody can give or spend money, but to give it to the right persons, to give the right amount of it, and to give it at the right time and for the right cause and in the right way, this is not what anybody can do, nor is it easy."

With Aristotle the Greek ideal attained its highest expression. Plato beheld it with a finer passion, perhaps, colored by a beauty not quite of this world, and endowed with an atmosphere not wholly human. He might have expressed that passion in the words of Sophocles: "O that my lot might lead me in the path of holy innocence of thought and deed, the path which august laws ordain, laws which in the highest heaven had their birth, neither did the race of mortal man beget them, nor shall oblivion ever put them to sleep; the power of God is mighty in them, and growth not old!" And Plato did say of his perfect State: "In heaven there is laid up a pattern of such a city, and he who desires may behold it, and, beholding, govern himself accordingly. But whether there really is or ever will be such an one is of no importance to him; for he will act according to the laws of that city and of no other." Aristotle beheld it with a calm confidence untouched by suspicions of its remoteness. For him it was the ideal of the best life attainable by man: best because it embodied the exercise of man's greatest capacities, and attainable because it was grounded in the indications of these capacities themselves, the existence of which guaranteed it without the need of other support.

Greek ethics, beginning with the Sophists and culminating in Aristotle, substituted thus for the current and traditional morals the conception of the best life for man in the light of his natural needs, surroundings, and capacities. Its dominant ideas were balance and intelligence. It was an ideal at once of conduct and of education. Wherever Greek influence went, — and that means throughout Western civilization, — ethical inquiry felt its impression. The conception of the best life, the terms in which it was expressed, the means by which it might be reached, the sanctions which might be urged in its support, — these things might vary, but reflection on morals tended to substitute for traditional practices a conception of the best life, or to suffuse these practices with a senti-

ment springing from the vision of it. Often these ethical reflections presented an astonishing contrast to the popular morality of the times which produced them; and this contrast has been so heightened by the imagination of many historians that we are wont to think of the centuries which marked the beginnings of the Roman Empire and the spread of Christianity as centuries of moral debauchery, and to regard their ethical ideals as protests wrung from despair. It is saner to think of them in the main as the continuance of the Greek habit of mind. The two ethical philosophies which are regarded as characteristically Roman, the Stoic and the Epicurean, received their initial impulse from Greek thinkers and spread under Greek influence and instruction; Neoplatonism was Plato revived and molding Jewish philosophy; Christianity itself, under Greek influence, came to think of Jesus not only as the Messiah, the bringer of comfort and salvation, but also as the pattern of perfection, the founder of a kingdom wherein membership constituted the best life.

Of all these ethical tendencies, Stoicism (*q.v.*) and Epicureanism have perhaps the best right to rank as ethical philosophies. The ideal of the one, conceived as the resolute will, and of the other, as the sensitive disposition, were grounded in a consideration of man's needs and capacities in view of his surroundings. These ideals have become violently contrasted in men's imagination. The Stoic, as Seneca (4-65), Epictetus (first century A.D.), and Marcus Aurelius (121-180) have pictured him, stands free from the allurements of passion, undaunted by calamity, self-poised, his soul steadfast and resolute to do his part in the world "whether God or atoms rule." The Epicurean, as the fine character of Epicurus (*q.v.*) (341-270 B.C.) himself and the poetry of Lucretius (96-55 B.C.) formed him, is open to the joys of life, his soul attuned and sensitive to the solicitations of happiness, his mind freed from cosmic obligations, since nature, being but matter continually reorganized according to changeless laws, is indifferent to all its products, and yet affords the instruments to happiness, if care is taken to discover and employ them. Contrasted as these ideals are, the one tending toward insensibility and the other toward dissoluteness, they involved an identical discipline, the understanding of human nature and the control of its propensities. Consequently both Stoic and Epicurean could find the aim of education to lie in the development of personality, and value its content and methods as these contributed to that aim.

For the development of ethics Christianity is especially noteworthy for its exaltation of new virtues. Aristotle emphasized such human excellences as wisdom, temperance, courage, justice, high-mindedness, liberality, and friendship. Christianity taught meekness, self-sacrifice, service, charity, mercy, peace, long-

suffering, forgiveness, faith, hope, and love. In so teaching, it did more than lengthen the list of the fruits of the spirit. It tended emphatically to alter for reflection the philosophical view of things. The world, in its conception, had become somehow soiled, so that men could not behave toward one another as beings exulting in the pride of life. They faced one another as creatures needing help, consolation, and comfort. They faced, too, a God who would be to them as a father if they, as children, would submit themselves in meekness to his parental care. Thus there has been in the ethics of Christianity the sense that human relations have been determined by an overwhelming calamity which spoiled and debased nature, making it unfit to be a source of inspiration and a sustainer of happiness, putting men rather in desperate need of one another's help and of salvation. There has been, in contrast with this life, the vision of the City of God, on which men should set their affections, and in the radiance of which the joys and toils of the present become insignificant and petty. It afforded an ideal which could comfort and ennoble, but which could also render men insensible to the demands of this life and indifferent to the possibilities of natural goodness. Its training was of the spirit in the paths of peace by the means of grace. So that when Christianity first possessed the world, it did not turn men's minds toward a knowledge and conquest of nature in the interest of human happiness. (See CHRISTIAN EDUCATION.)

Yet the sense of the futility of all things earthly should not be set down as a thing peculiarly Christian. While we are justified in regarding the ethical ideals of the Greco-Roman period as a continuation of the Greek habit of mind rather than as a protest against a widespread depravity in human affairs, we must recognize that they were generally marked by a sad world-weariness. They were so often the ideals of tired men. Various reasons have been assigned for this. Perhaps we find the clew to the matter in the fact that the general imagination was dominated by the idea of imperial conquest, of the restless expansion of the arms and power of Rome. Great victories could arouse great enthusiasms, but those victories tended more and more to be nothing but the subjugation of uncivilized hordes which imposed upon the Roman a burden of administration without contributing to the intellectual life of the time. The greatest energy was spent upon a task which yielded little spiritual reward beyond the consciousness of the successful handling of matters of routine. The conquest of barbarians by Romans afforded none of the great stimuli to creative imagination which marked the robust defense of Greeks against the Persian. The fruits of war were booty and the task of so organizing savage crowds that future trouble

might be avoided; they were not the consciousness of a nation saved by its own efforts for its own destiny. The things of the mind were supported by patronage rather than by the quickened intelligence of a people. A multitude that could not amuse itself had to be amused by administrative ingenuity. Life tended more and more to become artificial. It is clear that to Marcus Aurelius, who said that "even in a palace life may be well lived," the survey of imperial possibilities afforded no other prospect than another day of wearisome details, desperately in need of something refreshing, but finding only conventionality for its support. Not that men were generally conscious of such an atmosphere, but that in such they lived, and, breathing it, found it stifling,—if this was so, it is no wonder that men were tired and sought ideals of life which rested the soul, but did not inspire.

The Middle Ages, as we are wont to regard them, were possessed by Christianity, but by Christianity organized and administered by the Church and joined with the Empire in modifying the destinies of Europe. So dominant was that possession, and so frequently has history been written in terms of it, that the remarkable difference between the morals of men in their everyday life and the ideal of the best life as it found expression in the Church is overlooked. That ideal Mr. Bryce has thus described: "A life in the Church, for the Church, through the Church; a life which she blessed in mass at morning and sent to peaceful rest by the vesper hymn; a life which she supported by the constantly recurring stimulus of the sacraments, relieving it by confession, purifying it by penance, admonishing it by the presentation of visible objects for contemplation and worship—this was the life which they of the Middle Ages conceived of as the rightful life of man; it was the actual life of many, the ideal of all." But rarely has there been a time when human relations were marked by so much inhumanity and sordid worldliness, and yet which could own an ideal so unworldly. To that ideal men turned to seek enlightenment and instruction. In the shelter of the Church schools were founded. The teachers were clerics, and even when universities were established, with their characteristic institutional independence, the teachers still for the most part were members of some religious order, whether they taught medicine, law, rhetoric, physics, or theology. The more the learning of the Middle Ages became organized, the more it modified and expanded the ethical ideal. This is seen, for instance, in Abélard (*q.v.*) (1079–1142) and Thomas Aquinas (*q.v.*) (1224–1274). The former, under the title "Know Thyself," treated morality as an independent science based upon the will and conscience; and the latter regarded the State once more as an instrument for human perfection in this life. But most significant, perhaps,

is the work of Roger Bacon (*q.v.*) (1214?-1294). Part VII of his *Opus Majus* is a remarkable discussion of moral philosophy. It ends with the exaltation of Christian ideas as supreme; but it discusses civic morality and personal morality in the light of history. On these topics Bacon dwells at length because of "the beauty of the subject and the rarity of the books treating of it." Aristotle is his great authority, but he speaks of his search for Seneca, long unknown to him "and probably to others," and quotes him frequently. He affirms that admirable truths on the subject of personal character and conduct have been set forth by heathen writers, which put Christians to shame. While his work is exceptional, it indicates a new and growing interest in the ethical reflection of the time.

There were also influences independent of the Church which contributed to the enlargement of ethical conceptions. The institution of chivalry, with its ideal of the knight without fear and without reproach, its emphasis on courtesy, gentleness, succor of the oppressed, and respect for women, aroused an admiration of new virtues as embodied in the warrior who was also a gentleman. And such organizations as the Hanseatic League, arising earlier than the thirteenth century, and formed in the interests of safer trade and more intelligent commercial and industrial relations, began to make the demand for ethical recognition in a domain of human activity hitherto almost completely neglected by the moral philosopher. Its noon has been long delayed, but its dawn was early.

It is apparent that modern ethics was not confronted with a dearth of ideals. It possessed the moral philosophies of ancient times, and the heritage of the Middle Ages. Indeed, many a modern book is but a commendation of the long-familiar, a discussion of the best life and of the virtues; and moral education has often been conceived as the study of classical literature. Yet it is not to the rewriting of old themes, however fresh and invigorating, that we should turn for the modern emphasis. It was not for new ideals that modern ethical philosophers searched the scriptures and their own lives, but for a new authority, new methods, and new instruments. The Church ideal, although, as has been noted, there were tendencies in ethics which made for its modification, had acquired during the early years of Christianity and during the Middle Ages a superhuman authority resting upon an institution considered divine. Neither the authority nor the institution endured without challenge. The forces that weakened them—the expansion of men's minds through study, the steady, if slow, growth of a first-hand knowledge of nature, the strife between popes and emperors, the growth of nationalities, the discovery of new parts of the earth—weakened them gradually, but the consciousness that

they had been weakened to the point of inadequacy was comparatively abrupt. Francis Bacon (1561-1626), Descartes (1596-1650), and Hobbes (1588-1679) (*qq.v.*), for instance, write with the appreciation of the need of new foundations which is the outcome not merely of a gradual preparation, but also of sudden and revolutionary insight. Francis Bacon may be said to have raised a new ideal, but it was an ideal of the organization of the instruments at men's disposal for the attainment of the best life. These were primarily science, industry, and the arts. Bacon provided for the Church, leaving its authority undisturbed in those directions which science, industry, and the arts do not touch; but for these enterprises he claimed an independent domain, free from authority and tradition and founded squarely upon attainable human experience. Like Plato, he could sketch a perfect State, but in science, industry, and the arts it was founded, and in their interests organized. Descartes, confessing his willingness to submit his opinions to authority, proclaimed under cover of that confession his belief in the equal and natural ability of all men to distinguish between good and bad, true and false, and insisted that what men need in their concerns is not the guidance of authority, but a method for profitably conducting their thoughts and experiences. Hobbes attacked the idea of authority itself, and found it resting ultimately on the mutual consent of men unwilling to trust one another when left to their own natural devices; for the natural condition of mankind is, he thought, a war of every man against every other, and, "which is worst of all, continual fear and danger of violent death; and the life of man solitary, poor, nasty, brutish, and short." Authority, once established, he would have absolute, but he grounded it solely on nature, and justified its existence solely as an institution which makes for peace among men. Work like all this was not the beginning of a new era, but it proclaimed the full consciousness of one. Progress was openly arrayed against tradition, and it has fought a conquering battle ever since. That battle has been stubborn, and is still continued, but to-day it is a commonplace to affirm that authority rests on an accommodation and consent, that method is but organized experience, and that the primary instruments of human welfare are science, industry, and the arts.

The history of modern ethics is the history of the increasing recognition by moral philosophers of these principles. It has been, moreover, a history tangled and confused, for the spirit of modern ethics has never been completely the spirit of the institutions which have possessed the power and resources of modern times. It has had to win resources and power by revolution and compromise. It was thus marked, as we are wont to say, by an intense individualism, since it was the

spirit of persons rather than of institutions. Three hundred years after Francis Bacon and Hobbes, an emperor can still claim that he is an instrument of the Lord and not a creature of politics, that he holds his crown by the grace of God, and not by the will of a people or a parliament. Bishops and earls still sit in the House of Lords, not because they are statesmen, but because they are bishops and earls. Impulses toward civic improvement, the remedy of public evils, and the enlargement and betterment of education still find their chief stimuli in individual enterprise or in unofficial organizations. Similar illustrations might be cited from other departments of civilization. They reflect, and perhaps largely by way of reminiscence, how progress has made its way through revolution and compromise. Modern philosophy itself reflects the same picture. Descartes is its accredited father, but he left it a legacy of traditional problems which he himself had inherited, but had not discovered. Indeed, modern philosophy as a whole presents a confused combination of intellectual insight and problems which get their major significance from the fact that men once discussed them. And so, if we consider modern personality, the character of the typical modern man, we find it to be the product of readjustment rather than of singleness of vision. Progress was the spirit of the modern period, but the history of that period is the history of revolution and compromise. This, we may say, was inevitable, but there are indications that we have entered upon a new period where the demands of progress are no longer a call to arms, but the welcome vision of better things.

It was natural that individual moralists of the modern period should reflect its general tendency. Spinoza (1632-1677) is in many respects very typical. His principal contribution to philosophy bears the title *Ethica*. Its fourth book presents a way of life based on a knowledge of the passions of men as these affect human relations and as they can be controlled by reason. It is thoroughly democratic in outlook. In order to attain well-being, he tells us elsewhere (*Tractatus de Intellectus Emendatione*) that it is necessary to understand nature, "and also to form a social order such as is most conducive to the attainment of this character by the greatest number with the least difficulty and danger. We must seek the assistance of moral philosophy and the theory of education; further, as health is no insignificant means for attaining our end, we must also include the whole science of medicine, and, as many difficult things are by contrivance rendered easy, and we can in this way gain much time and convenience, the science of mechanics must in no way be despised. But, before all things, a means must be devised for improving the understanding and purifying it, as far as may be at the outset, so that

it may apprehend things without error, and in the best possible way." All this is conceived in the modern spirit, but Spinoza entitles his fourth book *Human Bondage*. The fifth book is entitled *Human Freedom*, and there Spinoza pictures the best life as a rapturous love of the mind for God, a kind of passionate medieval mysticism. This ideal he grounds in a metaphysical argument concerning substance and attribute, essence and existence, the finite and the infinite, nature and God. His ethics is a compromise between modernity, medievalism, and antiquity. Kant (*q.v.*) (1724-1804), too, is typical. He conceived the moral law to be the principle implied in all reasonable behavior, and thus a basal principle of human nature. But, as if this were inadequate, he finds its own important implications to be God, freedom, and immortality and a "kingdom of ends" which one could never quite reach by enthusiastically trying to improve society. Thus it was that attempts to found ethics upon human nature, human needs, human relationships, and to organize conduct in the interest of progress and a broad view of the possibilities of improving the conditions of life were so frequently turned into attempts to harmonize progress and tradition. Again, we may say this was inevitable, we may say it was wise; but it must be appreciated if we are to understand how modern moral philosophy so often attempted to legitimize progress, and yet hinted that the best life is attainable without it; or how the philosophy of Hegel (*q.v.*) was at once a bulwark of tradition and an inspiration to Karl Marx.

It would be inadequate, even in a general sketch, to let modern ethics go solely with this comment upon its dominant characteristic, for it was fertile in ethical problems, in attempts to discover why man is or should be moral. Besides opinions of the types already noted, there were men who looked for some natural sense or feeling or faculty or intuition, back to which could be traced the propensity to pass moral judgments upon conduct. Thus Hume (1711-1776) could appeal to the natural feeling of moral approbation; Adam Smith (1723-1790) to the natural sympathy aroused by an appreciation of the varied situations in which men find themselves; Reid (1710-1796) to a moral faculty; Kant (1724-1804) and T. H. Green (1836-1882) and their many followers to principles of judgment, native and intuitive; Spencer (1820-1903) to egoistic and altruistic impulses; and the long line of British utilitarians, with such prominent names as Bentham (1748-1832) and John Stuart Mill (1806-1873), (*q.v.*), to the natural desire for happiness. Such ideas as these were worked out by many, and in a variety of ways. On the continent of Europe they have been generally coupled with philosophical speculation and formalistic classification; in England with psychological analysis and practical affairs, so that there utili-

tarialism, with its emphasis upon happiness and the greatest good of the greatest number, has become nationally characteristic.

Particular mention should be made of the work of Henry Sidgwick. His *Methods of Ethics*, first published in 1874 (sixth edition, 1901), is written in the consciousness that the problem of ethics has become a problem in methodology, the ways and means of attaining the best life and the virtues, rather than the discovery of what is good or the foundation and authority of morals. He states in his preface that the work claims to be an examination "of the different methods of obtaining reasoned convictions as to what ought to be done which are to be found — either explicit or implicit — in the moral consciousness of mankind generally: and which, from time, to time, have been developed, either singly or in combination, by individual thinkers, and worked up into the systems now historical. I have avoided the inquiry into the Origin of the Moral Faculty — which has perhaps occupied a disproportionate amount of the attention of modern moralists — by the simple assumption (which seems to be made implicitly in all ethical reasoning) that there is something under any given circumstances which it is right or reasonable to do, and that this may be known. If it be admitted that we now have the faculty of knowing this, it appears to me that the investigation of the historical antecedents of this cognition, and of its relation to other elements of the mind, no more properly belongs to Ethics than the corresponding questions as to the cognition of Space belong to Geometry." Many have thought that the work of Sidgwick utterly ignores the inquiries which give to moral philosophy its chief and characteristic importance; but the historian sees in it the expression of a growing conviction that the best life is naturally disclosed in that prospect of better things which a progressive society envisages, that the virtues are virtues solely because they are types of human excellence historically exhibited and individually attainable in the relations of man to man, and that consequently the only moral *problem* is the concrete and particularized problem of method.

This conviction has in recent years steadily grown in intensity and in general recognition. We may still, however, discover, as in every period of human history we do, a great discrepancy between the habits and customs of men and the moral ideas which their literature and moral philosophy disclose; but he who reads and he who is engaged in any enterprise for the improvement of human relations can recognize that the primary demand to-day is not for edification, but for enlightenment. The priest still goes to the slums, but there goes with him a demand for more air and more light. Men still carry comfort to sick and wayward souls, but there go with them societies for the prevention of disease, of over-

crowding, of poverty, of excessive toil, of the unwise treatment of children, of almost every evil which can distort vision or sap energy. These societies appeal to the public conscience, but they seek to awake it not so much by exhortation as by the concrete exhibition of existing evils and the methods of remedying them. Public officers are *expected* to administer their trusts wisely, not solely because such is their duty, but primarily because they are public officers. In general, virtue is no less desired or esteemed, but vice has become more intolerable. Although revolution and compromise remain in practice, although habits and customs clash with insight and vision, the ethical inquiry of to-day may perhaps claim that it is freeing the conception of progress for singleness of vision. One of the most recent textbooks in ethics (Dewey and Tufts, 1908) closes with these words: —

"Science will succeed in pointing out the specific causes for many of the moral evils from which we suffer. Poverty, crime, social injustice, breaking down of the family, political corruption, are not all to be accepted simply as 'evils' or 'wickedness' in general. In many cases their amount may be greatly reduced when we understand their specific causes and apply a specific remedy. But the great reliance is upon the primal forces which have brought mankind so far along the line of advance. The constant remaking of values in the search for the genuinely satisfying, the constant forming, criticizing, and reshaping of ideals, the reverence for a larger law of life and a more than individual moral order, the outgoing of sympathy and love, the demand for justice — all these are the forces which have built our present social system, and these must continually reshape it into more adequate expressions of genuine moral life if it is to continue unimpaired or in greater vigor. We do not know in any full sense whence the life of the spirit comes, and we cannot, while standing upon the platform of ethics, predict its future. But if our study has shown anything, it is that the moral *is* a life, not a something ready-made and complete once for all. It is the new and serious situations which call out new vigor and lift it to higher levels. Ethical science, tracing this process of growth, has as its aim not to create life — for the life is present already, — but to discover its laws and principles. And this should aid in making its further advance stronger, freer, and more assured because more intelligent."

The aim of this article has not been to write a history of morals or a history of ethical philosophy. It has been rather to sketch the important ethical ideas as they have appeared in history and influenced the minds and educational ideals of men. To trace in detail how modern ethical ideas have affected modern education would involve the writing of the history of that education. For what that history reveals is the growing recognition of the spirit of progress. The steady broadening of the course of study, the slow breaking down of the idea that one type of education is adequate for everybody, the growth of industrial education and vocational training, the carrying of the school to all classes of society and continuously into new fields of activity, the revolution wrought in discipline, the professional training of teachers — such things not only reflect the spirit of modern ethics, but

point once more to the close connection which has always existed between moral insight and educational advance. Yet history discloses a steady decline of the importance attached by educators to specifically moral instruction. Even in our colleges and universities the course in ethics has lost the preëminence it once had. This is often regarded as a misfortune, but in the light of history it may be set down as the recognition that the young are taught to be moral not merely by precept and example, but by a lively acquaintance with the specific problems which beset life and by a training in the solution of them. Or it may be set down as the recognition that the study of good and bad, right and wrong, in general, is but one of many ways to strengthen the desire for the good and make known the best ways by which the goods of life may be secured and disseminated. Since the existence of the good and of various means for its attainment constitutes a natural incentive to morals, it may be claimed that there is no specific morality which can be taught.

**Academic Status of Ethics.** — Since the days of Plato and Aristotle, ethics has been regarded in the general classification of knowledge as a branch of philosophy. It should be remembered, however, that the scope of philosophy has been gradually restricted as special sciences have attained independence of general systems of thought. Yet, great as this restriction has been, ethics has not yet succeeded in establishing itself as an independent science, but remains along with logic, metaphysics, and aesthetics, as one of the parts of philosophy. This fact has determined the place which ethics has held in the general arrangement of college and university studies and its affiliations with other departments of knowledge. Even when it is taught in public schools as a part of general education, its connection with philosophy has been evident. For many years in American colleges a course in ethics, usually known as moral philosophy, was prescribed for all students, and this prescription is still common, although far from as general as formerly. For the advance of ethical inquiry the close identification of ethics with philosophy is not advantageous, for it is evident that any comprehensive appreciation of moral progress can be secured only through acquaintance with general history and with such subjects as economics, politics, sociology, and anthropology. The more intimate and increasingly recognized relation of ethics to these subjects will doubtless alter its future status as an academic discipline.

**ETHICS, PROFESSIONAL.** — See PROFESSIONAL ETHICS; TEACHING AS A PROFESSION.

**ETHNOLOGY.** — See ANTHROPOLOGY.

**ETIQUETTE, EDUCATION IN.** — See CHIVALRIC EDUCATION; GENTRY AND NOBLES, EDUCATION OF.

**ETON COLLEGE.** — The school which was attached to this college, or which formed rather the principal object and end of the college, is probably the greatest alike in size and results which the world has yet seen. In England, while many schools are called royal and dubbed royal foundations, this is the only royal foundation in the full sense. It not only received royal recognition in its title, and in being endowed out of nominally royal, but really public, possessions, but it was actually built with moneys out of the privy purse, and endowed with lands, some of them confiscated to the royal purse, but some also bought out of it by the personal effort and at the personal expense of a king. By letters patent of Oct. 11, 1440, King Henry VI, then eighteen years old, having just taken on himself the government, "as a sort of first-fruits," to "show like his ancestors his devotion to the Church," founded in the parish

church of Eton "not far from our birth-place" in Windsor, "the Kings College of Oure Ladye of Eton besyde Wyndesore" to consist of a Provost, ten priests (the fellows), four clerks, "six chorister boys, daily to serve at divine worship, and twenty-five poor and needy scholars to learn grammar there," and "twenty-five poor and disabled men to pray for the souls of his father and mother and all his forefathers and all the faithful departed; also a Master or Informator in grammar to teach the said needy scholars and all others from any part of England coming there, *gratis*, without exaction of money or anything else." The college was licensed to hold property up to the value of 1000 marks (£666, 13s. 4d.) a year, equivalent to about £20,000 a year now, and the Provost, two fellows, four choristers, two scholars, two clerks, two almsmen were named in the charter. Shortly after, on Feb. 12, 1411, King Henry founded another college at Cambridge University, consisting of a Provost and twelve Scholars or fellows, by the name of the King's College of St. Nicholas of Myra, the prototype of the boy-bishop, the patron saint of schoolboys, who is still worshipped by children under the name of Santa Claus, was Dec. 6, the King's birthday. There was in Eton church before 1425 a chantry of St. Nicholas, and it is quite possible that the chantry priest of this church was also, as was common, a grammar schoolmaster. This may have partly suggested the choice of Eton for the site of the college school. There was at first no organic connection between Eton and the Cambridge college. The immediate model of the two colleges was the college school at Higham Ferrers in Northamptonshire and the College of All Souls at Oxford, founded by Henry Chicheley, Archbishop of Canterbury (*q.v.*), Henry's godfather, in 1422 and 1432 respectively. But these were only copies on a smaller scale of the two colleges of St. Mary founded by William of Wykeham, Lord Chancellor of England and Bishop of Winchester at Oxford, then and now called New College, in 1379 and at Winchester in 1382, in which Chicheley had received his own education. Winchester College was the first collegiate church (*q.v.*) in which instead of church services education for boys was made the first object of the corporate body. On Mar. 5, 1440-1441, the first installment of the endowments was given to Eton, chiefly consisting of Alien Priors (*q.v.*). A good many of them had been sold or leased to great persons, and Henry had to buy these to give them to his college as William of Wykeham and Chicheley had done for their colleges. In 1441 Henry visited Winchester to see the working of the school, and as a result, when starting the school at Eton, probably about Michaelmas, 1443, — two years, 1441 to 1443, being employed in building the college

and school — he appointed as Provost William Waynflete, who had been headmaster of Winchester for eleven years to Michaelmas, 1441.

Another Winchester scholar, William Westbury, came from New College to be headmaster in 1442. Statutes were made for Eton and the Cambridge college on July 10, 1443, in the same words, with small exceptions, as those for Winchester and New College, and five scholars, one ex-scholar, and one commoner of Winchester were admitted among the first eleven scholars of Eton. So large a part did Winchester play at Eton that the first three provosts, twelve out of the first twenty-five headmasters and eight of the ushers or second masters, and probably a good many more, came from Winchester. The statutes enlarged each college to the same size as Winchester and New College, *i.e.* to a provost and seventy scholars, besides the ten fellows, while at Eton there were also added, in imitation of Winchester, twenty Commoners (*commonsales*) who were to be sons of noblemen or special friends of the college, and thirteen outside scholars of the kind known afterwards as servitors, who got their education and board in return for acting as servants to the fellows and headmaster. Henceforth King's College, Cambridge, was to be exclusively manned from the "College Roiall" of Eton, as New College, Oxford, was from Winchester College. Enormous sums were spent, chiefly out of the revenues of the duchy of Lancaster, on building and rebuilding, on an ever-increasing scale, the college, and particularly the church of Eton. But it remained unfinished, when in 1452 the first attack of insanity fell on Henry.

During the Wars of the Roses a great part of the endowment was taken away by Edward IV, and in 1463 by Papal Bull the college was annexed to St. George's, Windsor, and for some four or five years the school ceased. In 1467 it was restored by the efforts of Westbury and Waynflete, then Bishop of Winchester, with Edward IV as founder instead of Henry VI, though since the days of the Tudors Henry VI has been reinstated. The revenues were so diminished that the provost got £30 a year instead of £75, and the headmaster £10 instead of £16, and there were only seven fellows instead of ten. This perhaps hastened rather than retarded the development of the school into a great public school for the upper classes and the aristocracy, who, while paying nothing for their education, as the school was a free grammar school open without tuition fees to all comers, paid large sums for boarding in the houses of the fellows and in the town of Eton, whence they came to be called Oppidans. As at Winchester so at Eton the "poor and needy" scholars were scions from the first of the professional classes and the country gentry, relations of judges and civil servants and well-to-do people, while as early as 1529 Richard Lord Grey of Ruthyn was at the school, prob-

LOGGAN'S VIEW OF ETON COLLEGE (1688).

ETON COLLEGE. (FROM THE SOUTH.)

ably as a commoner, and a young Paston, of the family of the Paston letters, as an Oppidan (about 1479).

The earliest indication of the number of the Oppidans, who rather than the scholars have made the school famous, is in the will of Provost Lupton, provost from 1501 to 1510. Most of the college buildings and the whole of the great quadrangle except the chapel were built by him or in his time. First came in 1503-1504 "Long Chamber," in which all the seventy scholars slept in one long room, now cut up into separate rooms, and which

"Contrived a double debt to pay,  
Bedrooms by night and living-rooms by day."

Next, about 1512, a new, now Old or Lower School, in 1515 the chantry on the north side of the church, known as Lupton's chantry, in which he and many later provosts lie buried, and in 1517 the Provost's Lodgings and the great red-brick central tower called Lupton's Tower. By his will, Feb. 23, 1540, Lupton gave "a hundreth children of the town *Sd.* a piece." There is no other indication of numbers till the first extant school list, that for 1678, when there were 207 boys, including the choristers. Only one was a nobleman, the Scotch Earl of Stirling, and there were three baronets. Sir Robert Walpole, the first Etonian Prime Minister, was a collegier, and was on the roll of King's College in 1695. In the next school list, that for 1718, the numbers had risen to 399. The first William Pitt, afterwards Earl of Chatham, was there in 1717. The numbers sank again to 244 in 1745, went up to 498 in 1766, of whom 50 were sons of peers, down to 230 in 1770 after a rebellion in which 156 boys left the school, including a future Prime Minister, William Grenville, who was sent back by his father to be flogged and expelled. In 1836 the numbers stood at 441, while ten years later they were 777, in 1891, 1007, and in 1908, 1045.

Of the curriculum of the school no very definite information is forthcoming before the sixteenth century. But we know that it consisted in the study of the Latin classics and the writing of Latin verses from the record of a payment of 10*l.* in 1474 "for the binding of a school-book, viz. Ovid," and from a letter of William Paston in 1479 in which he gives a specimen of his versifying. In 1486 a school Vergil was recovered which had been furtively taken away, apparently by a dismissed headmaster. In 1528 the "Form order and usage taught in the Grammar School at Eton" was directed to be followed in the free grammar school at Cuckfield, Sussex, enlarged in that year and the "Form" is annexed to the deed of endowment. It gives the curriculum in six classes. The first class learnt Stanbridge's *Latin Grammar Rules* in English, and did "small and easy Latins." The second did Cato's *Moralia*, the third and fourth Terence and Erasmus' *Colloquies*, the fifth and sixth

Vergil, Sallust, Horace, and Ovid. They all wrote Latin prose and verse. No Greek is mentioned. But a little earlier the *Vulgaria* of William Horman (*q.v.*), headmaster of Eton 1485-1495 and, after an interval at Winchester as headmaster, 1495-1501, fellow and vice-provost of Eton, published in 1519, give evidence of Greek being taught there; and Sir Thomas Pope, founder of Trinity College, Oxford, writing in 1556, says Greek was taught at Eton when he was a boy there. No Greek occurs in the time-table sent by Dr. Cox, headmaster in 1530, to Saffron Walden School in Essex. Even in the time-table of Malim, headmaster in 1561, Greek grammar was only learned by the two highest forms, VI and VII, and no Greek authors are mentioned. It is not till some notes of Anthony à Wood's, made about 1669, that Demosthenes, Homer, and "Zenophon" appear among the authors read. At that time Greek prose was practiced by translations out of Latin into Greek. In 1765 Dr. James' time-table shows that the Sixth Form translated Homer into Latin verse. Theocritus, Aristophanes, and Greek plays were read. Latin verses were still the chief object. French was taught out of school, as was also drawing. It was not till 1851 that mathematics was made a part of the regular school work, nor till 1869 that natural science was introduced, and the mathematical, science, and French masters were raised to the same status as the classical masters. Under Dr. Warre (1884-1905), the unity of the school was supposed to be preserved by a community of bondage to the Greek Testament, being read by all for one hour every Monday morning. Now, under Dr. Edward Lyttelton, it is possible to be admitted to Eton without "compulsory Greek," and to pass through it with German instead of Greek in the Army Class—a rather recent addition to the school which produced the Duke of Wellington and Earl Roberts in the regular classical mill. The Army Classes number over 100 boys. Classics still predominate, 184 out of the first 240 boys specializing in classics, which now include, however, French, English history, and English literature, as well as mathematics and classics proper.

It was of course a libel when Huxley said that Eton only taught good manners and a gentlemanly proficiency in cricket. It is not even certain whether its cultivation of cricket—to use the word as including games and sports in general—is due to its being the school of the aristocracy, or whether it is the school of the aristocracy because of its cultivation of cricket. It was always to a large extent the school of the court because of the royal patronage extended to it, and its neighborhood to Windsor and to London; but until the second half of the eighteenth century it was less the school of the aristocracy in general than Winchester in the seventeenth or than Westminster in the eighteenth century. It became pre-

eminently the school of the aristocracy because of the beauty of its site, the superiority of its buildings, and the charm of its spacious playing fields, but chiefly because on the whole the boys were much better treated than at other schools. The system of dames' houses had already begun in 1561, when Malin says that there were monitors at each "hostises" (hostess') house "to stop chiding or wrangling and to enforce talking Latin." The houses being of moderate size and kept by ladies, much less barbarism flourished there than in Long Chamber at Eton or at Westminster or the much more barrack-like Commoners at Winchester or "schoolhouse" at Rugby.

As early as 1506 the famous playing fields, playing meads, or playing lees, as they were at first and more properly called, since they were grass meadows and not fields, *i.e.* arable land, occur in the accounts. Before that there was little encouragement of games, and the only forms of exercise were a march out to Montem, later known as Salt Hill, a hill about a mile from the college, with special outings for getting may on May Day and gathering nuts in September. Little of either could be gathered by the school now. About the same time the boys began to perform plays, a Latin play, presented by the master at Christmas, with a little later an English play presented by the usher. From Horman's *Vulgaria* (1519) we gather that the boys learned to swim and play football "with a ball full of wind," quoits, and tennis. Cricket does not appear before the reign of Elizabeth, and then as a town game at Guilford in Surrey. By Elizabeth's reign Montem had sunk into an annual celebration at which new boys were initiated with actual and Attie salt; and afterwards became a mock-military maren at which the salt took the form of guineas, collected from passers-by and those who came to see the fun, for the benefit of the captain of the school, the head collegier. Robert Boyle, "father of chemistry and uncle of the Earl of Cork," when at Eton about 1630, played at tops and ball and was given sweets by the provost. In 1765 cricket, fives, and tennis are the principal games mentioned in the *Nugæ Etonenses (Eton Trifles)* of that year. But battledore and shuttlecock, peg-tops, hop-scotch, marbles, hoops, puss-in-the-corner, hunt-the-hare, and chuck-farthing are also mentioned. It is a disputed point incapable of definite solution, whether, when Gray, in his *Ode on a Distant Prospect of Eton College*, written 1742, asks "who chase the rolling circle's speed" he meant who bowls hoops, or who runs after the cricket ball. These "who urge the flying ball" were no doubt the football players. It was not till the nineteenth century that the playing of cricket became a cult and rowing a profession. The former began with the matches against Harrow School, first started in 1822, and against Winchester College in

1826, and still played annually, the latter since 1854 at Winchester and Eton alternately, the former at Lord's Cricket Ground, London. Boating as a profession and not a mere amusement began with races against Westminster School in 1826, and continued till 1848, when the Thames steamboats stopped Westminster rowing. Since then Henley Regatta has been the object of the Eton eight. Though some other schools, such as Bedford, Radley, and to a small extent Winchester and Cheltenham, now row, the Oxford and Cambridge boat race still depends chiefly on which university is, for the time, favored by the Eton oarsmen. At football Eton has two games of its own, "at the Wall," the grand match between Collegers and Oppidans being played on Nov. 30, and the field game, which is one of the elements from which the Association game was developed at Oxford. A Rugby football team and an Association team are now started for some interschool matches. Tennis has disappeared. Rackets reigns in its stead.

But great as the part played by games has been in making the Etonian and the English public school system, it is after all to the excellence of its teaching that Eton has owed its position. Even in the days when Keate (*c.* 1830) pretended to teach 198 boys in one form, the lessons being often interrupted by singing and throwing paper pellets or even stones, the out-of-school teaching by "my tutor" was most efficient for those who chose to learn. Many of the tutors inspired in the boys a far more lasting love of letters and a more effective stimulant than the more ordered and systematic compulsion of class teaching. The names of George Canning, Prime Minister in 1827, the Marquess Wellesley, Governor-General of India, of Gladstone, three times Prime Minister, and Lord Chief Justice Coleridge, as eminent in learning, in the school magazines, and the school debating society, commonly called "pop," as they were in afterlife in the House of Commons or the law courts, are alone enough to show that Eton education was no bad one.

The advertisement thus received from its ten prime ministers, its twenty-two governor-generals of India, and its innumerable cabinet ministers, attracted "the thanes," and the thanes attracted the rest. On the whole, Eton has led and still leads the van of the public schools on its merits. The authorities there have on the whole been more amenable to public opinion and more pervious to new ideas than those of other prominent schools, especially in the domestic life of the boys, but also in the adoption of new subjects and new methods in teaching.

**EUCLID (EUKLEIDES).** — The greatest teacher of geometry of ancient times, and the author of one of the world's most influential textbooks. Practically all that is known of his life is given by Proclus (410-485 A.D.) (*q.v.*), who says: "Not much younger than these [Hermotimus of Colophon, and Philippus of Mende, who were pupils of Plato] is Euclid, who composed the *Elements*, collecting many of the theorems of Eudoxus (*q.v.*), perfecting many of those of Theætetus, and also demonstrating with perfect certainty what his predecessors had but insufficiently proved. He flourished in the time of the first Ptolemy, for Archimedes (*q.v.*), who closely followed the first [*i.e.* Ptolemy the First, or Ptolemy Soter], speaks of Euclid. Furthermore it is related that Ptolemy one time demanded of him if there was in geometry no shorter way than that of the *Elements*; to whom he replied that there was no royal road to geometry. He was therefore younger than the pupils of Plato, but older than Eratosthenes and Archimedes; for the latter were contemporaries with one another, as Eratosthenes somewhere says." Another Greek writer, Stobæus, tells a story that expresses the educational value placed by Euclid upon geometry: "Someone who had begun to study geometry with Euclid, when he had learned the first theorem, asked, 'But what shall I get by learning these things?' Euclid called his slave, and said, 'Give him three pence, since he must make gain out of what he learns.'"

From the first of these fragments we gather that Euclid lived after the pupils of Plato (who died in 347 B.C.), and before Archimedes (who was born c. 287 B.C.), and in the reign of Ptolemy Soter (who reigned from 306 to 283 B.C.). He must therefore have flourished about 300 B.C. He probably studied at Athens, and certainly taught at the great school of Alexandria, in Egypt. He wrote not merely on geometry, but also on the theory of numbers and other mathematical subjects. It is, however, by his *Elements* that he is chiefly known. Proclus, in speaking of this work, says that there are "in the whole of geometry certain leading theorems, bearing to those which follow the relation of a principle, all-pervading, and furnishing proofs of many properties.

Such theorems are called by the name of *elements*, and their function may be compared to that of the letters of the alphabet in relation to language, letters being indeed called by the same name in Greek" (*στοιχεῖα*, *stoeicheia*). This characterizes the work of Euclid, a collection of the basic propositions of geometry, and chiefly of plane geometry, arranged in logical sequence. Euclid included in plane geometry between 160 and 175 propositions, the manuscripts varying in details. The distinctive feature of his work, compared with modern textbooks, is that he mingles his problems and theorems, endeavoring always to show how a figure is to be constructed before he considers any theorems relating to that figure. We, on the other hand, usually assume the possibility of constructing the figures, until we have a body of theorems upon which the proofs that our constructions are correct can be built. Euclid's treatment of proportion is purely geometric, and is considered too difficult for beginning pupils to-day, being replaced by an algebraic treatment. This modern method is confessedly less mathematically rigorous than the ancient one.

While we have in modern times improved the phraseology of Euclid, simplified the treatment of a few propositions, and made more usable textbooks for beginners, we have not improved upon the rigor of Euclid, nor have we materially changed his basic propositions. Although he was not completely rigorous in all of his steps, he was more nearly so than modern textbook makers, and his geometry is liable to remain for all time as a standard upon which others can improve in details of bookmaking, but upon which no one will greatly improve in the essential features. **EUDOXUS (408-355 B.C.).** — A distinguished mathematician of the Athenian school. He was born at Cnidus, studied at Tarentum under the Pythagoreans, went to Egypt with Plato, and finally taught at Athens. To him seems to have been due most of the fifth book of Euclid (*q.v.*), the book that treats of proportion. He was much interested in the theory of the "golden section," the division of a line in extreme and mean ratio. He also perfected the "method of exhaustions" in geometry, which had been suggested by Bryson about 430 B.C. Essentially this means that, in the case of the circle, we may inscribe and circumscribe regular polygons, continually doubling the number of sides, and approaching

the circle as a limit, thus exhausting the area between the polygons and the circle. Eudoxus also wrote on astronomy, and his observations were highly esteemed by his successors.

**EUGENE BIBLE UNIVERSITY, EUGENE, ORE.**—A coeducational institution, incorporated in 1895 and offering courses for the training of ministers and the study of the Bible, and maintaining also preparatory, music, and art schools. Part of the studies may be taken at the University of Oregon. The degree of A.B. is given at the end of the four-year classical ministerial course, and a diploma at the end of the three-year English ministerial course. There are twelve instructors on the faculty.

**EUGENICS** (Greek *εὐγενής*, "well-born").—A term modeled after "mathematics," "economics," etc., now the accepted designation of the new science of which the late Sir Francis Galton (*q.v.*) was both father and apostle. Galton first baptized his great idea, as he himself informs us, with the name "stirpiculture," which, fortunately, he abandoned for "eugenics," a word that has found easy lodgment in English and some other European tongues. The matter had been crystallizing in his mind since about 1865, and in 1883 (*Hum. Fac.*, p. 4) he defined the new science thus: "The investigation of human eugenics, that is, of the conditions under which men of a high type are produced"; and for him, somewhat later, "eugenism" expressed "the aggregate of the most favorable conditions for healthy and happy existence." The ideal of "eugenics" was thus the breeding of men of a high type and the creation for them of an environment in which they could live healthily and happily. It is to be regretted that this clear and simple definition of the science could not be preserved in its integrity, although its author harks back to it again and again. In 1904 (*Sociol. Pap.*, 1905, p. 4) Galton explained eugenics as "the science which deals with all influences that improve the inborn qualities of a race; also with those that develop them to the utmost advantage." A year later (*Sociol. Pap.*, 1906, p. 3) he wrote: "Eugenics may be defined as the science which deals with those social agencies that influence mentally or physically the racial qualities of future generations." The *Eugenics Review*, the organ of the Eugenics Education Society, has as a motto a somewhat different definition: "Eugenics is the study of agencies under social control that may improve or impair the racial qualities of future generations either physically or mentally"; and the motto of the Francis

Galton Laboratory for National Eugenics at the University of London defines "national eugenics" in just the same words. The popularity of eugenics has been, until lately, of rather slow growth. Indeed, it is a curious fact that not until some of its devotees had, in some way or other, touched the keys of nationalism and of race, did it take seriously in certain quarters. The scare of "race-deterioration," so largely a myth, but propagated skilfully by the militarists, resulted in a boom for the new science, the declared object of which was the production of men better constituted physically in particular, and, therefore, better food for powder. A decrease, *e.g.* in the average height of recruits, which may be in itself no bad thing at all, but an actual advantage evolutionally, and the "alarming frequency" of alleged "stigmata of degeneration," that disqualified men for military service, but did not seriously unfit them for pursuing the more necessary and more satisfying arts and activities of peaceful life, were made the most of, and eugenics gained thereby in vogue, if it lost in fidelity to the real principles of human evolution. Thus in Britain, as in Germany, "national eugenics" and "racial eugenics" were born and baptized with much less than an omnium-blessing. "Anglo-Saxon eugenics," too, is not unheard of. In this way eugenics has taken on a patriotic instead of an anthropological color in some places, and its aim is not so much the production of men of a high type as it is the physical betterment of youth annually sacrificed to the god of war. It is fair to say, however, that many eugenicists, like President Jordan, of Leland Stanford University, are outspoken in their denunciation of the folly of civilization in thus sending its best blood to destruction. Eugenics in the service of war is a travesty upon human intelligence; it is the victories of peace, "no less renowned than war," with which eugenics must be in eternal alliance. The generic condition of mankind is peace, not war; and eugenics is a generic science.

The eugenic idea *per se* is nothing new in the world. What is new about it, or, rather, what has yet to be added, is its humanization, for, even in our own day, it smacks too much of the stud. Theognis of Megara, the protagonist of the Dorian aristocracy of the middle of the sixth century, *b.c.*, in a poem addressed to young Cynus, wondered that horses and cattle were so finely and men and women so poorly bred; and, two centuries later, Plato, the great Greek philosopher, in his *Republic*, sketched a "proto-eugenic" system, which, happily, stands no chance of ever being adopted by any sane community of human beings,—the distance some of the Greek peoples went in the direction indicated by him accounting, doubtless, in part at least, for the subsequent extinction or degeneration

of the Hellenic race. Nor has eugenics been confined altogether to the civilized sections of mankind. Mr. A. E. Crawley (*Eugen. Rev.*, Vol. I, pp. 275-280) has called attention to "primitive eugenics," as exemplified, *e.g.* among the Fijians, the Australian Blacks, etc., where artificial methods, in the form of taboos and the like, "favor the best results for birth and rearing." This is in addition to the "natural sexual selection" (not promiscuity) in vogue, which makes for the best unions. Of the general environment of savagery, Mr. Crawley remarks, "the only drawback to its eugenic perfection is a certain irregularity about meals." Out of this eugenic Garden of Eden man has banished himself by adopting the artificial instead of the natural life. Mr. J. G. Frazer, in a recent monumental work on primitive sociology in certain of its most remarkable aspects (*Totemism and Exogamy*, 1910, Vol. IV, pp. 109, 168), emphasizes the existence among savage peoples of "artificial methods deliberately devised for preventing the marriage of near kin." He does not hesitate to say that exogamy, "in the form in which it is practiced by the lowest of existing savages, the aborigines of Australia, presents a curious analogy to a system of scientific breeding." These savages, he thinks, "egregiously wrong in theory," but "fundamentally right in practice," really present "an unconscious mimicry of science." The ends accomplished were wise, even if the thoughts of the men who initiated the devices employed were very foolish. Such things almost make one believe that occasionally men ignorantly but successfully get into touch with the guiding currents of the life process itself. Evidently "national eugenics" has not a little to learn from "primitive eugenics." This is especially true, when one considers the safeguards thrown about the pregnant woman and the woman who has been recently a mother by savage and barbarous peoples all over the globe. Rights and privileges which modern legislators still hesitate to confer upon her are there her portion by immutable public opinion. Here, as so often in other matters, an unspoiled primitive people reflects better the essential morality and justice of mankind than does a Greek philosopher, *blasé* even at his early stage of the world's history.

It was quite natural that England, where class and heredity still count for so much in society and in political institutions, should be the modern vitalizer of the eugenic idea; and as natural also that democratic America should be inclined to criticize before accepting its dogmas. Galton, "the father of eugenics," illustrated admirably his science, for he was, indeed, well-born, — cousin of the immortal Charles Darwin, who was himself the child of a cousin-marriage. In a sense, he "recapitulated" eugenics. Rarely in human history has it occurred that the founder of a new

science, himself a man of genius, has been the close kin of men of genius. Moreover, Galton was very fortunate in associating himself with Professor Karl Pearson, whose "mathematical contributions to the theory of evolution" have made him justly famous. The combination of Galton and Pearson does not often occur at the birth or the beginning of the propagation of a new idea. And, beside all this, like Darwin, Galton did not belong to the academic proletariat, but was able to a considerable extent to finance his reform. It was from his pocket that the salaries of the Research Fellow and the Research Scholar in the Eugenics Laboratory at the University of London came, and his bounty was evident in other directions as well. Facilities for the publication of results of investigations along eugenic lines and in allied fields of research have been provided, such as *The Eugenics Review*, *Biometrika*, the various monographs issued from the Laboratory of Eugenics, etc. By will Galton left the chief portion of his fortune to establish a chair of eugenics in the University of London, the first occupant of which is to be Dr. Karl Pearson. A Eugenics Education Society has been founded, whose objects are declared to be as follows: (1) Persistently to set forth the national importance of eugenics in order to modify public opinion and create a sense of responsibility in the respect of bringing all matters pertaining to human parenthood under the domination of eugenic ideals. (2) To spread a knowledge of the laws of heredity so far as they are surely known, and so far as that knowledge might affect the improvement of the race. (3) To further eugenic teaching at home, in the schools, and elsewhere. In Germany, the corresponding society is *Die Internationale Gesellschaft für Rassen-Hygiene*, whose members among many other things conducing to eugenism, "agree that, before entering on marriage, they will submit to a medical examination as to their fitness for the marriage state, and, if pronounced unfit, will abstain from marriage, or, at all events, from parenthood" (*Eug. Rev.*, Vol. II, p. 91). The German periodical concerned with eugenics is the *Archiv für Rassen- und Gesellschafts-Biologie*. The American Breeders' Association (founded in 1903) has now a eugenic section devoted to the human aspects of breeding. Under the auspices of this section subcommittees of experts are now engaged in the investigation of the feeble-minded and insane, while others yet to be constituted will study deaf-mutism, eye-defects, etc., from the eugenic point of view. Much "pre-eugenic" work has been done in America in connection with personal purity "campaigns," the "Indiana movement," and other efforts to combat alcoholism, the "social evil," syphilis, etc., but eugenics itself is broader and deeper than all these efforts at social and individual "reform," and cannot

act as the mere subsidiary of race, sect, class, or the like. Naturally, in America, emphasis has been laid upon environment. Davenport (*Eugenics*, 1910) tends to ignore the controversy between heredity and environment in practical eugenics; and Burbank, looking upon heredity as "stored environment" (*Training of the Human Plant*, 1907, p. 88) considers that "in child-rearing environment is equally essential with heredity," a view that departs far from the opinions of some of the British eugenicists. It is an American, too, Mrs. E. H. Richards, who has provided the name for the science of the eugenic environment. Her book, *Euthenics, the science of controllable environment* (1910) treats of "the betterment of living conditions through conscious endeavor for the purpose of securing efficient human beings." The remarkable power of environment, as revealed everywhere in America will make it difficult for the advocates of "social surgery" to secure the enactment of their more radical legislation, although sterilization of the unfit, so warmly advocated by so distinguished a British eugenicist as Havelock Ellis, and already in vogue in parts of Switzerland, in the state of Indiana, and is approved by many American physicians and others. Legal infanticide and voluntary destruction of the weak, abnormal, etc., have not yet won popular approval. Dr. F. A. Woods, however, (*Pop. Sci. Mo.*, 1910), has called attention to "the laws of diminishing environmental influence," and "diminished value of modification as evolution proceeds." This would apply especially to human psychic phenomena. Burbank and others would keep children out of school till after the tenth year. Sir Francis Galton, himself, and other prominent eugenicists have been careful to disavow any sympathy with the idea of creating by a *coup d'état* "eugenic state" on the Platonic model. Mr. F. C. S. Schiller (*Eug. Rev.*, Vol. II, p. 16) condemns Plato's *Republic* as "hopelessly impossible." Plato's proposed state regulation of marriage with official "ballot-stuffing" in the process of mating by lot to the advantage of "superior persons of each sex," and legal infanticide for the offspring of "inferior parents," is so thoroughly unevolutional in its character that science must always relegate it with other chimeras to the lumber pile of impracticable as well as unhuman "reforms." But Plato was not content with this alone, for his scheme involved also a more than Nietzschean disregard of mother love and the destruction of the sense for the child in the individual parent, as well as the abolition of the whole individual family life. In the mind of the great philosopher (if he really believed in his own plan, which, we may charitably think, is doubtful), "conscious parenthood" found no place. Here is where modern must differ from Platonic eugenics. Galton, himself (*Memories*, 1908, p. 311), noting that "the most common misrepresentations now are that its

methods must be altogether those of compulsory unions, as in breeding animals," expresses the view that, while forcible interference with the propagation of the unfit and the constant introduction of degenerate stock is not inconsistent with democratic theory, and may come in course of time, compulsory marriage is an entirely different thing, the ethical justification of which, as well as the scientific, is yet absolutely without proof. The very title of Dr. Saleeby's book, *Parenthood and Race-Culture*, shows where he stands upon certain questions. Eugenics, as the science of breeding for posterity, must have parenthood as its ideal, reverence for motherhood and reverence for fatherhood; the determination that those who are to live the "good life" shall be born of good stock into a good environment. This means infinitely more than the "stud-farm" or the "social surgery" theory of eugenics. An eminently sane view of practical eugenics obtains with such American writers and investigators as Professor Davenport, whose little book should be read by every one desirous of knowing the relationship of eugenics to biology, and of finding out, so far as is now discovered, what things may and what may not be bred into or out of human beings. Both in Europe and in America, eugenics is in process of being humanized. The preservation of the family (eugamy) must form a part of what has been called the "chivalry" of eugenics. All eugenic proposals that would injure ultimately its integrity are in themselves non-eugenic and unevolutional, for whatever relationships may elsewhere obtain, in this sphere of activity "man is man, and beast is beast." The ultimate *eubiosis* must be thoroughly human.

In various parts of the world, the eugenic "campaign" is interfered with, or modified by, the prevalence of certain more or less local phenomena. Such, e.g. are in England "the race deterioration scare," already referred to, and the "new woman" movement; in France the low birth-rate; in Germany the educated proletariat; in parts of Scandinavia the low marriage rate; in the Latin countries the existence of multitudes of celibates of both sexes connected with the Church; in English America, the divorce problem and the "race suicide" question. Considered evolutionally, however, most of these complications are of a temporary or a merely incidental nature, and eugenics, rightly understood, has nothing to fear from them in the long run. This is particularly true of so-called "race suicide" in America, as Phillips (*Univ. of Col. Studies*, Vol. VII, 1909-1910.) has recently pointed out in his very interesting discussion of this topic about which certain great Americans have worried so much. And in England Dr. Saleeby believes the low birth-rate a sign of progress rather than otherwise.

In their "eugenic program" the various peoples of the world differ, and will perhaps differ for a long time; and when such new and

powerful peoples in the sphere of human activities in the large as the Japanese, Chinese, etc., begin in earnest real eugenic labors, it is reasonable to suppose that new contributions of great value will be made by them to the science of breeding men and women of a high type, not to say in the processes by which their healthy and happy existence will be assured and sustained. In certain countries of Europe, Switzerland and France in particular, the endowment of motherhood and fatherhood and the taxing of bachelorhood are in great favor. Mothers are allowed leave of absence during childbed, without loss of pay, when they are school teachers, government or municipal officials, etc., and in some places officials who at the age of twenty-five or twenty-nine are still unmarried are compelled to forfeit their positions, while those in civil life have a double military duty to face. This is in marked contrast with English America, where marriage is a reason for exclusion from college, as also from the ranks of the teaching profession (for women) in most parts of the country, while it is not uncommon for presidents of educational institutions to proclaim themselves loudly as eugenists or opponents of "race suicide," although in the faculties of their universities or colleges absolutely no distinction in the matter of salary, even in hard times, is made between "the bachelor without encumbrances" and "the man with a family." And the institutions of highest rank, devoted to research, are seemingly the worst offenders. Science has yet to recognize the family.

Naturally enough, the young science of eugenics has had to quarrel with some of the older and more strenuous or more popular theories and speculations of the age, and to make its alliances and combinations with others of these. And sometimes it has suffered more at the hands of its friends than at those of its foes. All Darwinians, Lamarckians, Mendelians, De Vriesians, — the many varieties of evolutionists, mutationists, etc., — have not seen eugenics with the same eye, nor have they been equally cordial in welcoming or equally zealous in rejecting it. Galton, himself, healthily anti-Nietzschean, sums up the matter on this point in these words (*Memories*, p. 323): "Man is gifted with pity and other kindly feelings; he has also the power of preventing many kinds of suffering. I conceive it to fall well within his province to replace natural selection by other processes that are more merciful and not less effective. This is precisely the aim of eugenics. Its first object is to check the birth rate of the unfit, instead of allowing them to come into being, though doomed in large numbers to perish prematurely. The second object is the improvement of the race by furthering the productivity of the fit by early marriages and healthful rearing of their children. Natural selection rests upon excessive production and wholesale

destruction; eugenics on bringing no more individuals into the world than can be properly cared for, and those only of the best stock." Eugenics, moreover, in that it cares for both the individual and the nation, has the virtues of both charity (in the true sense) and statesmanship. It is both ideal and practical, humane and human.

The disputes concerning the nature and mechanism of heredity, the possibility of the inheritance of acquired characters, etc., have sometimes been lively, even within the eugenic group of scientists themselves. Galton and Pearson, the former from his studies of men of genius and their relationships, the latter from his statistical investigations, etc., are partisans of heredity, going almost as far as the American Dr. Woods, who maintains (*Pop. Sci. Mo.*, April, 1910) that "experimentally and statistically there is not a grain of proof that ordinarily environment can alter the *salient mental and moral traits* in any measurable degree from what they were predetermined to be through innate influences." Both have recently objected to the quite absurd idea that the British House of Lords and the hereditary nobility of the Empire were object lessons in eugenics (*Eug. Rev.*, Vol. 11, pp. 3, 81). Heredity by no means necessarily implies primogeniture: in fact, it almost appears to point a little in the direction of gavelkind. Both Sir Francis Galton and Professor Pearson are convinced, as the result of numerous researches carried on by themselves, or more or less under their direction, that with respect to tuberculosis, insanity, crime, and possibly certain other things, there is "a pathological weighting of elder children," which would call into doubt alike the institution of the small family and the selection of the first born for hereditary positions. Selection from all the children would here be the truly hereditary and eugenic process. One of the common beliefs of generations past that "clergymen's sons go to the devil," or are, at least, very inferior individuals, has been proved false through the investigations of Welldon, even if the later studies of Schuster on the promise of youth and the performance of manhood have shown that "there is reason to suppose that the bar is a profession which attracts abler men than does the church." Professor Pearson thinks his numerous and extensive investigations indicate that "the mental characters in man are inherited in precisely the same manner as the physical," and that "our mental and moral nature is, quite as much as our physical nature, the outcome of hereditary factors." Interesting data furnished by the eugenic school are the studies of correlation between mental and physical characters and between mental and moral attributes, etc. Some of the results obtained merely confirm or refute, as the case may be, old folk thoughts or "guesses at truth"; some others are still of very doubtful

validity. A fair criticism of some of the studies of Pearson is made by Bateson (*Proc. Roy. Soc., Lond.*, 1901), who says that they have to do "with normality rather than with evolution."

The results of Mr. Heron's researches concerning the influence of defective physique and unfavorable home environment on the intelligence of school children are rather surprising. It was found "impossible to assert that defective intelligence has largely its source in unfavorable home environment or in defective physique," and that "home environment, as measured by clothing, cleanliness, nutrition, stature, and weight, cannot be the chief determining cause of the differentiation of intelligence; nor is defective physique the cause." Even more remarkable are the results of the Elderton-Pearson study of the influence of parental alcoholism on the physique and intelligence of the offspring, in accordance with which very slight traces of deleterious influences are perceptible, and a considerable number of cases must rather be counted in favor of the alcoholic parent. This curious result certainly needs reinvestigation. It will be noticed that many of the studies of the British eugenists are as decidedly in favor of "nature" as are corresponding investigations in America (see CRIMINALITY IN CHILDREN) in favor of environment. The cousin-marriage question (the results of Huth's and Sir G. Darwin's investigations as to the harmlessness of such alliances between thoroughly healthy individuals of healthy stock have never been seriously attacked) has been made more interesting by the data obtained in Fiji by Thomson (see *Eug. Rev.*, Vol. I, p. 279). Among this fine, healthy race, "habitually marrying their first cousins," no evil effects are discoverable (and they outrank the natives of other parts of Fiji where the practice of such marriages is not in vogue), and it appears that the children of parents whose parents were brother and sister have advantages over those of parents whose parents were the offspring of two brothers or two sisters respectively.

The question as to the proper social atmosphere for the eugenic idea is one which all eugenists are not agreed on. Some, like Herbert, wish to tie it up to socialism, believing that "the socialistic state" is the only one in which it can ever attain any sort of perfection; others, like Whetham, confess a secret belief that "eugenics would best be furthered by an enlightened and aristocratic Toryism." Others, again, with Mügge, express the opinion that the fit thing to do is to marry "the eugenic science," discovered by Galton, to "the eugenic religion," promulgated by Nietzsche, and thus make certain the breed of the superman (or rather the overman). Not a few are mightily disturbed about the coming of the woman, and are altogether fearful of its effects upon "man, who is, after all, more important than

woman in the history of mankind." There are eugenists also who are not quite sure but that eugenics may after all turn out to be a sort of device of "nurture" instead of "nature," injurious in reality to the great selective forces of nature, interference with which on the part of man tends to be so calamitous. They will not go as far as Archdall Reid in watching cold-bloodedly the weeding out of the weak, nor will they, on the other hand, with Dr. Salceby, attribute so much virtue to the elimination of the "race poisons" to which millions are sacrificed every year.

There are eugenists who scoff at love as a mere frailty of many human beings, and they have left it out of account in the pros and cons of eugenics. But love, who laughs still at locksmiths and has done so from time immemorial, is not to be disposed of so easily. Galton is much wiser than some of his disciples, and has felt the force of the argument that humanity would hardly be likely to decree the death of the finest product of the long line of sentient development from the protozoa to the conception of God himself. He has made it clear that he entertains no such delusion, for he says (*Sociol. Papers*, 1906, p. 51): "I regret that I did not express the distinction that ought to have been made between the two stages, that of slight inclination and that of falling thoroughly into love, for it is the first of these rather than the second that I hope the popular feeling of the future will successfully resist." If eugenics can always retain a sense of the divinity of the greatest human passion, and sustain the test of Shakespeare's immortal dictum, all may, perhaps, be well. A. F. C.

**EULER, CARL PHILIPP** (1828-1901). —

A prominent German teacher of physical training; was born at Kirchenbollenbach, near Trier, Rhine Province, and studied philology and history at the universities of Bonn and Berlin. In 1852 he took the course for the training of teachers of gymnastics in the Royal *Zentral-Turnanstalt* under Captain Rothstein (*q.v.*), devoting himself especially to the study of anatomy and physiology, which he considered indispensable for the teaching of gymnastics. In 1854 he was called to the famous school of Schulpforta to teach languages and history, as well as gymnastics, fencing, and swimming. He succeeded in imbuing with the love of physical exercise not only the students, but also the younger teachers of the institution. His reputation soon earned for him a call to the *Zentral-Turnanstalt* in Berlin (1860), where he became involved in a controversy with the director of the institution, Captain Rothstein (the so-called *Barren-Streit*). Rothstein, an admirer of the Swedish system of gymnastics, removed from the gymnasium all horizontal and parallel bars, as well as other apparatus commonly used by German teachers, on the ground that the exercises on these apparatus were unhygienic. Euler opposed this attack on the German system, and the matter created such widespread attention that it was brought up in the Prussian legislature, where the famous physiologist Du Bois Reymond (*q.v.*) championed the cause of the native school of gymnastics against the Swedish system. Finally the controversy was decided in favor of Euler by an expert opinion given by the highest medical authority in Prussia.

Besides teaching in the *Zentral-Turnanstalt*, Euler directed the physical instruction in a number of other schools, such as the Joachimsthal Gymnasium, the Wilhelm Gymnasium, and the Royal Female Teachers' Seminary. He did much for the introduction of physical training for girls and for the instruction in swimming. From 1865 on he was sent by the government on annual tours of inspection to report on the condition of the teaching of gymnastics in the various Prussian provinces. In 1892 he was made a *Royal School Councillor*,

and in 1901 he died in Berlin. Euler's literary activity, especially in the field of the theory and the history of gymnastic instruction, was very large and important. Through him the life and works of Jahn (*q.v.*) were first made really accessible. He wrote an extensive biography of Jahn (*Friedrich Ludwig Jahn, sein Leben und Wirken*, Stuttgart, 1881), and published an excellent edition of his works, with an introduction and explanatory notes (Hof, 1883). Euler's *Geschichte des Turnunterrichts* (*History of Gymnastic Instruction*), Gotha, 1891, is very valuable. His last and most important work consisted in editing his large *Enzyklopädisches Handbuch des gesammten Turnwesens* (*Encyclopedia of Gymnastics*) 3 vols., (Vienna, 1894-1896), a considerable part of which was written by himself. F. M.

**EULER, LEONHARD** (1707-1783). —

A noted Swiss mathematician, born at Basel and educated under a scholar of great scientific ability, Johann Bernoulli. Some of the Bernoulli family being called to Russia by the empress, they used their good offices to secure a place for Euler. In 1733 he became professor of mathematics at St. Petersburg, and began a work full of promise, and, as it turned out, equally full of important results. The climate seems to have been responsible for a difficulty of vision that soon developed, and in 1735 he lost the use of one of his eyes. Six years later he was called to Berlin by Frederick the Great, and remained there for twenty-five years. He then returned to St. Petersburg, where he passed the last years of his life in total blindness. Euler was a prolific writer, especially in the line of analysis. He was one of the first to make extensive use of the imaginary in algebraic work, and to him is due the valuable formula  $e^{i\phi} = \cos \phi + i \sin \phi$ . His most important works are the *Introductio in Analysin Infinitorum* (1748), *Institutiones Calculi Differentialis* (1755), *Institutiones Calculi Integralis* (1768-1770), and the *Anleitung zur Algebra* (1770, with later French and English translations). To Euler is due not a little that has in late years developed into theories of importance, as in the calculus of variations, the study of the beta and gamma functions, and the modern theory of primes. His work in astronomy, optics, and physics was also of far-reaching importance. D. E. S.

**EUREKA COLLEGE, EUREKA, ILL.** — A coeducational institution which grew out of the Walnut Grove Seminary, established in 1848 and incorporated as a college in 1855.

Preparatory and collegiate departments are maintained. The entrance requirements are equivalent to about fourteen units of high school work.

**EUSEBIUS** (260-340). — Historian, apologist, exegete, critic, scholar, and theologian, was born about 260 A.D. at Cæsarea and educated in the Christian school of that city. Cæsarea was then the metropolis of Palestine, and its great school, founded by Origen (*q.v.*), rivaled that of Alexandria. Here Eusebius was a pupil of Dorotheus, a famous teacher of liberal mind and Greek culture. He formed one of the most beautiful friendships known to history with Pamphilus, the first wealthy Churchman who spent his riches in the accumulation of a library. In this unrivaled collection, Eusebius revelled with the delight of a bookworm, and over this school he presided for many years. The most learned man of the fourth century, he became Bishop of Cæsarea in 313, and was soon recognized as one of the foremost men in the Church. His reputation as the most learned of its members and as the chaplain and confidant of the Emperor Constantine made him a prominent figure in the Council of Nice, at which he delivered the opening address. His attitude toward the Arians during this council and afterwards was severely criticized, but he has been acquitted of error by the general consent of the learned men of later times. His mind was acquisitive rather than productive, broad rather than deep, and his spirit was tolerant. He sought out the elements of truth in all philosophic systems and popular religions, and found in them a foothold for Christian teaching. Standing between the old pagan and the new Christian civilization, he strove to conserve the most precious remains of the past for the use and instruction of the future. He had the instinct of genius for choosing themes of permanent interest. With vast erudition and sterling good sense he drew from the storehouse of the past those things which it was worth while to preserve from oblivion. While his theological and exegetical writings are of solid value, he is best known by his *Ecclesiastical History*, which justly entitles him to be known as "the father of church history." It covers the first three centuries of Christianity, and is absolutely indispensable to the student. Its value lies not in literary merit, but in the wealth of materials drawn from original sources, and the wisdom and honesty with which they were used.

**EUSTOCHIUM, JULIA** (368-419). — Saint of the Roman Catholic Church, daughter of a Roman senator, whose wife Paula with her daughter was under the spiritual charge of St. Jerome (*q.v.*). To these women Jerome addressed his letters on education (esp. Ch. XXII), which form most important sources of information concerning early Christian education, especially of the monastic type. Both Paula and Eustochium were instrumental in founding and directing monasteries for women, and hence were important leaders in the early education of women.

**EVAGRIUS**. — Ecclesiastical historian; born at Epiphania in Syria, 536 A.D., and trained for the legal profession in the schools of the rhetoricians and grammarians. He practiced law with signal success at Antioch, and won for himself the surname "Scholasticus." His chief work was his *History*, covering the years 431 to 594, and intended as a continuation of the *Church Histories* of Eusebius and Theodoret. Though somewhat credulous, he had learned from Eusebius the importance of quoting the original documents, and has preserved many of great value to the student and historian. He took great pains in collecting materials, wove them into a spirited narrative, and exhibited many of the best qualities of a historian.

**EVANS, EVAN WILLIAM** (1827-1874). — Educator and author, graduated at Yale College in 1851; principal of the Delaware Literary Institute, and instructor at Yale College; professor at Marietta College and Cornell University; and author of a series of mathematical textbooks.

W. S. M.

**EVELYN, JOHN** (1620-1706). — English gentleman and author, who took considerable interest in education. He received his instruction from the village schoolmaster in the porch over the church at Wotton. He was a student at Balliol College, Oxford, 1637, but himself states that he was idle there. He was also a student of law at the Middle Temple, but, again, learned little there. From his travels he learned much, including French, Italian, and Spanish. At Padua, where he studied, he was elected *Syndicus Artistarum*, but was disqualified by proceeding on his travels. In 1667 Evelyn secured the Arundelian library of the Howard family for the new Royal Society, of which he was one of the early members. In the same year he obtained for Oxford from

Henry Howard the Arundelian Marbles. In 1672 Evelyn was secretary to the Royal Society. He is well known as a writer on medals, architecture, sculpture, landscape gardening. In 1656 Evelyn translated the first book of Lucretius into English verse, and in 1667 issued *Instructions concerning the Erection of a Library*, from the French of G. Naudé. His Diary (first published in 1818 and 1819) is very valuable in its references to current social life.

On the educational side, Evelyn wrote a letter, dated Sayes Court, Sept. 3, 1659, to Robert Boyle, proposing a plan for a mathematical college. He gives practical details for the living together of a small society for the purposes of study, and states that if he had not others depending on him: "I would cheerfully devote my small fortune towards a design, by which I might hope to assemble some small number together, who would resign themselves to live profitably and sweetly together."

In 1659 Evelyn published *The Golden Book of St. John Chrysostom, concerning the Education of Children*, Translated out of the Greek by J. E. Esq. (i.e. John Evelyn).

*Dictionary of National Biography.*

**EVENING SCHOOLS.** — Schools of various kinds, public and private, in which instruction is given chiefly to those who are prevented from attending day schools by the necessity of earning a livelihood. These schools, in general, offer educational opportunity along three lines: (1) A repetition of the work of the regular elementary and secondary day school; (2) vocational instruction, chiefly along commercial and industrial lines; (3) general informational and cultural instruction for those whose daily work offers little or no opportunities for such instruction. Nearly all countries have such schools at the present time, and they are materially helping in the education of the working people. One feature of special significance is the greater adaptation of these schools to the needs of the people than is found in the day schools, which are so largely bound down by traditional subjects and traditional methods. Since the needs of the people reached by these schools vary so widely, each country would naturally have a different type of evening school.

**Germany.** — The evening schools in Germany owe their origin to the establishment of Sunday schools for teaching religious truths to youth preparing for confirmation. These were first established by the Bishop of Samland in 1569. Under Frederick II secular subjects were introduced, and the schoolmaster became the teacher. In 1765, according to the General Regulations of the Catholic schools of Silesia, all persons under twenty years of age who had

left school were required to attend Sunday instruction in Christianity, and after this, for two hours, to attend lessons in reading and writing. In some places a general education was given, while in others, where the need of it was more marked, various kinds of industrial instruction were introduced. Gradually this instruction, instead of being given entirely on Sundays, was given on weekday evenings as well, and, while to-day there are still some schools which give instruction on Sundays, the majority of them are evening schools. These schools constitute the main part of the continuation school system of Germany, which, in turn, forms such an important element in the general system of industrial education of the country (*q.v.*).

**England.** — The first evening schools in England were, in all probability, private schools for the instruction of such as could not attend school during the day. Early in the eighteenth century the Society for the Promotion of Christian Knowledge (*q.v.*) issued a circular recommending masters and employers to appoint some hours in the evenings of certain days of the week to teach such grown persons to read as had neglected study. There is little information regarding evening schools during the eighteenth century, and while schools of this kind were established under private auspices and under the charge of benevolent societies, it was not until the nineteenth century that they began to become important. In 1806 an evening school for boys and girls who had to work during the day was opened at Bristol by the Benevolent Evening School Society. The instruction offered in this school was gratuitous, and only for sons and daughters of the laboring poor. The subjects taught were reading, writing, and arithmetic. Then for nearly forty years little was done in developing this kind of educational work; but in 1839 Bishop Hinds laid special emphasis on the importance of evening schools, and recommended that instruction in them be limited to those under sixteen years of age. After 1830 the Science and Art Department was largely instrumental in the establishment and extension of evening schools chiefly by means of grants of public money to those managers, teachers, and students who fulfilled the conditions laid down. In 1851 the Education Department first began to give grants to elementary evening schools, and in 1855 the first capitation grants were made to them. Payments were also made to teachers in these schools, but in 1861 teachers in day schools were forbidden to teach in night schools. The revised code of 1861 withdrew aid to teachers, but abolished the restriction on day school teachers. Capitation grants were made on average attendance, and payments were made for results of examinations in reading, writing, and arithmetic. During this time, and until 1893, schools received grants from both the Education De-

partment and from the Department of Science and Art. The result of the restrictions of the education department was to make these schools rely more on the department of science and art.

The attendance at evening schools increased up to the year 1870. In that year the act relative to evening schools set no limit on the age of students, nor was the work compulsory. The instruction given was almost entirely limited to elementary work, in that grants were given only for such work. Work of a more advanced character was, nevertheless, demanded by the students and given. School boards were not specifically empowered to conduct evening schools, but the times when schools should be in session were not defined, and hence the boards were left free to do as they pleased. The next year the grants were definitely limited to persons not over eighteen years nor under twelve years of age. This resulted in a decrease in the attendance. In 1876 the upper limit was raised to twenty-one years. In 1882 no grants were given except for those between the ages of fourteen and twenty-one. In the act of 1890 it was definitely stated that the principal part of the instruction need not be elementary. This resulted in a rapid development from elementary to advanced work. Shop instruction and special industrial subjects were introduced and became popular. Thus the schools more and more grew to be secondary in character. The public had refused to provide for such training in the public day schools, and it was inevitable that evening schools, responsive as they always were to the needs of the people, should take on the character of secondary schools for the masses. A further impetus was given in 1893, when a new code for evening continuation schools was published, widely extending their scope. In 1900 the Cockerton judgment (*q.v.*) declared it illegal for school boards to apply the Parliamentary grant for other than elementary subjects or for pupils above fourteen. While this decision deprived the evening schools of the grant for elementary education, it had nothing to do with grants from the Science and Art Department. By the act of 1902 it was definitely declared that "all instruction after 4 P.M. is secondary," thus definitely declaring that hereafter the evening schools should not receive grants as elementary schools. Elementary instruction was still provided, and grants made for it, but higher grants were paid for more advanced work. By this act the previous regulations regarding the evening schools were combined with the science and art regulations in so far as these affected the evening schools.

As at present constituted, no pupils are admitted who are not exempt from attendance at the regular day schools. The law requires all between the ages of five and fourteen to attend the day schools, unless they have attained a certain standard. The minimum age for

admission to the evening schools is twelve years, and very few pupils are under thirteen. The administration of these schools was formerly divided between the Science and Art Department and the Education Department. Now, as far as they are administered by educational authority, the Board of Education has complete charge. A great many of these schools, especially in London, were founded by the various guilds, and many are conducted in connection with the private technical schools throughout the country. These night classes often reach a far greater number of people than do the day classes. All these may receive grants from the Board, if their courses comply with the regulations. Each school is supported partly by local authority, either private or public, and partly by the public grants from the central government. At least twenty-five per cent of the expenditure of the school must be met by the local authority, by endowments, subscriptions, tuition fees, etc. In addition to these grants of money, prizes, and certificates are given to pupils who successfully pass examinations in the various subjects.

The question of charging fees has been in a very unsettled condition, schools sometimes charging fees and sometimes not. The tendency is distinctly in favor (1) of charging fees for all evening students; (2) of making fees for those under sixteen less than for those over that age; (3) of charging more for higher than for elementary subjects. It is found that a nominal fee is more likely to insure good attendance. The usual number of evenings per week is three, but in certain cases four or even five evenings are given. The ordinary hours are from 7.30 to 9.30, but in the commercial schools and some others they are from 7 to 9.30. This interval is divided into two, or in some cases into three periods. The session usually begins in the middle or latter part of September, and lasts until the end of April. A small number of classes continue until the middle of July, but very little work of a solid character is done after the end of April. Many schools do not begin until the first of November.

According to the code of 1905 the subjects in the evening schools are grouped in six divisions, as follows: I. (*a*) Preparatory and general: Reading, composition, writing, arithmetic, knowledge of common things, elementary principles of science, elementary drawing, life and duties of citizens, theory of music, and vocal music. (*b*) Literary and commercial: English, Latin, French, German, any other modern language, geography, history, economics, mercantile law and practice, commercial correspondence and office routine, book-keeping, shorthand. II. Art. III. Manual Instruction: includes woodwork and metal work. IV. Science: Any generalized or special branch of science, including mathematics, will be accepted if adequate. V. Home occupations and industries: Needlework, domestic

economy, cooking, dressmaking and cutting out, laundry work, dairy work, gardening, cottage industries, ambulance, home nursing. VI. Physical training: This aims at the general physical development of those instructed. Adapted to the age and sex of the pupil.

These are the subjects authorized by the Board for which grants are given. Few schools have all of these, nor is it intended that they should. On the other hand, other subjects than those mentioned may, at the discretion of the Board, be recognized. All schools must have at least two subjects, although no pupil is compelled to take more than one subject. (The industrial work of the schools is described in the article on industrial education.)

**France.**—The evening schools in France form a large part of the system of continuation schools. Taken together, they are called *éducation post-scolaire*, or *œuvres complémentaires*, and are included in the department of primary instruction. They were probably introduced from England in 1820, when an evening school was established in Paris. They were in a flourishing condition at about the middle of the nineteenth century; in 1867 there were 35,000 such classes, but after this there was a decline. In 1895–1896, 15,000 courses were offered, with an attendance of about 270,500, while in 1906–1907 there were 48,248 courses, with an attendance of about 600,000. These classes are held in the evenings, and generally in the public school buildings. Great freedom is allowed in the establishment and conduct of these classes. Any one who desires may open a class, provided he has the approval of the mayor of the commune, the prefect of the department, and the academy inspector. A decree passed Jan. 13, 1887, places the minimum age for admission at thirteen years. A strong feeling exists that attendance should be made compulsory up to seventeen years of age, and for a fixed annual term, but efforts to this end have so far failed. At present, any one attends who wishes and as long as he likes. Certificates of attendance are given, which carry some weight with certain employers, and prizes are often given by local authorities or by individuals. Aside from these there is nothing to induce or to compel attendance other than interest in the work itself or the social attractions of the classes. The classes for men and for women are usually separate, but mixed classes are frequently held in the larger places. It is difficult to secure enough money for this work. Small fees are often charged, but the people who most need the instruction are those who can least afford to pay for it. The state makes an annual appropriation for this work, which amounted in 1906 to 600,000 francs (\$120,000). The chief sources of support are private subscriptions and subsidies granted by local authorities. The teachers are, as a rule, public school

teachers, and usually serve without extra compensation. They do, however, receive official letters of recognition, diplomas, medals, decorations, etc., which are greatly prized by the recipients. The classes are divided into: (1) *cours d'adultes*, classes for illiterates, (2) *cours complémentaires*, continuation classes proper, and (3) *cours techniques*, technical classes. Many private societies also are engaged in maintaining evening continuation classes.

**United States.**—There are many agencies in the United States conducting evening schools of various kinds. Many private and endowed institutions are conducting very valuable schools in different parts of the country. Among these are the various Mechanics' Institutes (*q.v.*) and allied organizations, and such institutions as Pratt Institute and Cooper Union (*q.v.*) in New York City. The classes given under the auspices of the Y.M.C.A. and the Y.W.C.A. are of great value and reach large numbers of boys and girls, men and women. The instruction offered by these organizations differs widely, varying from classes in reading and writing to courses in plumbing, scientific advertising, automobiling, and almost every branch of industrial, technical, and commercial as well as cultural instruction. The great development in this country, however, has been in the public evening schools. No other educational agency is reaching so large a part of the working people as these evening schools. The history of these public evening schools may be roughly divided into three periods.

I. *Private Evening Schools.*—The first private evening school mentioned in the records for New York City is that taught or proposed to be taught by James Lyde in the custom-house in September, 1730. It was a "mathematical" school, and included such subjects as "arithmetic in all its parts, geometry, trigonometry, navigation, surveying, gauging, algebra, and sundry other parts of mathematical learning." But while this is the first private school, it must be noted that evening schools in connection with the public elementary schools were common, if not the rule, among the Dutch of New Netherlands and Colonial New York. They are thus found at New Amsterdam in 1661, Kingston in 1668, Flatbush in 1670, and thereafter. It seems probable from apprenticeship records that these evening schools were especially attended by those who were engaged in work during the day. The rates of tuition for evening instruction were higher than in the day school. (See NEW YORK STATE.) Private evening schools seem to have had their greatest development in the beginning of the nineteenth century. In 1823 the Public School Society passed a resolution permitting their teachers to hold evening schools in the school buildings at their own expense. Tuition fees were usually charged. In New England the first mention found of a pri-

vate evening school is a notice in the *Boston News Letter* of one kept by Mr. Samuel Granger in Boston in 1724. He taught "writing, accounts, and the mathematics." From 1750, at least, there are evidences that private schools where instruction was given in the evening were not at all uncommon. These schools were especially common from 1780 to 1815 or 1820. In Dorchester a school for apprentices in the paper mills and "other studiously inclined boys" was kept by Samuel Crane from 1790 to 1797. He also kept a day school. In Pennsylvania there is a record of an evening school in Germantown in 1702, which was kept by the learned Pastorius "for such as could not attend the day school." A night school is mentioned as having been conducted in Philadelphia in 1751, in which, besides the ordinary subjects, "geometry, navigation, and mensuration" were taught. From these references it seems probable that private evening schools were quite common in New England, New York, and Pennsylvania, at least during the latter part of the eighteenth century and up to 1820. Some of these were for apprentices, and all were for working people.

H. *Evening Schools founded by Benevolent Societies.*—Probably the first free evening schools in the country were established for slaves and other negroes by the Society for the Propagation of the Gospel (*q.v.*). One of these was started in Staten Island in 1715. From that time on others were conducted both in Staten Island and New York. In 1787 the Manumission Society also maintained schools for negroes in New York. In Philadelphia work among the negroes was prosecuted largely by the Society of Friends. In 1789 the Society for the Free Instruction of the Black People conducted an evening school for adult negroes. This school continued with some interruption up to 1835 or later. Other societies of Friends established schools of the same kind. In some cases the same societies conducted evening schools for adult whites and adult negroes. In Salem, in 1774, there was a school conducted under the charge of the selectmen and paid for out of the interest on money previously given for the support of schools and for the tuition of poor children. In this school, twelve boys were to be instructed free of charge on three evenings of the week. This was largely an affair of charity. The beginning of the real philanthropic movement in Boston and Salem seems to have been about 1810 or a little later. In 1814 and 1815 two charitable schools for girls were founded by an association of young women in Salem. In 1816 Sunday schools were first introduced into Boston, and for a time these gave instructions to poor boys and girls in reading and writing. These, while not evening schools, served to call the attention of the public to the need of instruction for boys and girls at work. Very soon serious objection was made to such secular instruction on the

Sabbath, and other time had to be found for it. It is probable that this helped to pave the way for evening schools later. In 1823 the selectmen aided the cause of evening schools by appropriating \$75 for such a school for young men over fifteen years old. There is nothing to indicate that this was considered in any way a part of the school system. From now to the time when evening schools were formally established, such work was mainly conducted by philanthropic and religious societies. In 1836 Warner Street Chapel in Boston opened a free evening school, which continued for twenty years at least, and was very successful. Several other schools were conducted by religious agencies during the same period. In 1856 the number in attendance on these schools was not far from 2500. Frequently the agencies in charge of these schools received aid from the city, sometimes in the form of free use of buildings, of heat and light, and often by direct appropriation of money. The schools were free, no tuition being charged. They were not, however, considered a part of the public school system, and were controlled by other agencies. The first indication of this movement in Pennsylvania might be said to be in the industrial evening school conducted by the Moravians at Lititz in 1754. Here boys who were employed during the day were taught "some useful knowledge" three evenings a week. In 1799 the young men who afterwards founded the Philadelphia Society for the Establishment and Support of Charity Schools conducted evening classes for apprentices, clerks, and others. Some young ladies also conducted evening schools among the poor at the same time. The schools for adult negroes and whites have been mentioned, and it is probable that other societies had schools for whites as well as negroes. About 1847 the Missionary Society of the Church of the Atonement, in Philadelphia, conducted the Logan Evening School. This had in 1850 an enrollment of 246. In 1850 the city appropriated \$2000 for the establishment and support of free evening schools, and from that time they have been conducted by the city. The beginning of the philanthropic movement in New York dates from about 1830. The records of the Public School Society show numerous requests for the use of the public school buildings for free evening schools. These requests came from private citizens and associations. In nearly every case they were granted. The need for such schools was so great that soon after, in 1833, the Public School Society undertook the work, and opened four schools for apprentices and others. They were quite successful, and were conducted for several years thereafter. But owing to the fact that the day school teachers were required to teach the evening classes also, and without additional pay, there were lack of interest and considerable objection on the part of the teachers. There

was some doubt about the right to expend public money for such schools, and in consequence they were discontinued. These schools were free and quasi-public; the money used for their support was taken from the general fund of the society, which was made up in part of public money and in part of gifts and bequests. After this there seem to be no records of evening schools until 1817. They may have been continued, supported by philanthropic agencies.

III. *Free Public Evening Schools.*—The free public evening school developed directly and naturally from the evening school controlled by philanthropic agencies and partly supported by public funds. The schools opened in 1833 in New York were free, and, in a sense, public, for they were supported in part from public funds. In 1847, at the urgent solicitation of the board of education, the legislature of New York passed a law empowering the board to conduct evening schools for males and authorizing the expenditure of \$6000 per annum for this purpose. Acting on this authority, the board opened six schools in November, 1847. These were in charge of a special committee on evening schools. They were kept open for a term of seventeen weeks, and had an enrollment of 3224. Admission was refused to hundreds. Thirty-one teachers were employed. In 1848 the legislature authorized the opening of evening schools for women and girls, and allowed an expenditure of \$15,000. This greatly increased the usefulness of the schools, and their development was rapid. Evening schools were also authorized in Brooklyn by the law of 1850, and were organized in Baltimore in 1840 by the board of education, when six schools were opened for apprentices and other young men. They were, however, discontinued in 1843. The reasons given by the board were (1) want of patronage, (2) expense, (3) application of the means for education of apprentices that should be used for the instruction of younger pupils. In 1856 they were again resumed. Louisville, Ky., was one of the first to experiment with public evening schools. In November, 1834, a small public evening school was opened, which was continued for two years and then discontinued, opened for one year in 1842, for another year in 1859, for three or four years in 1873, and finally established in 1882. Ohio was the first state to pass a law regarding the establishment of public evening schools (Section XVI of the act passed by the legislature of Ohio, Mar. 16, 1839). In accordance with this act there were opened in Cincinnati in November, 1840, three evening schools, which had a fairly continuous existence, being in session all but one year up to 1861. In 1855 schools for girls were also opened. So far as can be determined, no other city in Ohio opened evening schools in accordance with this law. When the common schools were reorganized in 1853, it was no longer made obligatory to

provide such schools, but it was left to the discretion of the school boards. By an act of the legislature of Massachusetts approved Mar. 29, 1847, permission was given to cities and towns to appropriate money for the support of schools for the instruction of adults in reading, writing, English grammar, arithmetic, and geography. In this act no mention is made of the time of day when such instruction would be given, and there is nothing to indicate whether it was intended to apply this to evening schools or not. Cities interpreted it variously. New Bedford opened two evening schools in December, 1848, which were supported from the regular funds, and Worcester opened three schools in 1849, also supported by public money. But when Lowell tried to do the same, the opposition was so strong that an injunction was obtained which stayed the payment of the money appropriated. The matter was definitely settled in 1857, when an act of the legislature formally authorized the payment of money for the maintenance of evening schools. It was some years before the attempts to establish them in Boston and Salem were successful. In Boston six schools were opened under the charge of a special committee in 1868, and the next year they were formally incorporated into the school system. In Salem the evening schools were finally taken over by the city in 1869. In 1883 Massachusetts passed a law compelling towns having 10,000 inhabitants or over to maintain elementary evening schools. Connecticut has a similar law. Since 1886 in Massachusetts, cities having 50,000 inhabitants or over have been under obligation to support an evening high school upon the petition of fifty or more residents over fourteen years old who desire to attend. In Indiana all cities of 3000 inhabitants or over must conduct evening schools on petition of twenty or more citizens. In New Hampshire all towns of 5000 inhabitants or over are compelled to establish evening schools on petition of five per cent of the voters. In Pennsylvania cities must conduct such schools on petition of twenty or more parents of children six years old or older. In Ohio, Louisiana, and Georgia permission is directly given to conduct such schools, and in several other states it is implied. Some of the other cities which opened public evening schools at an early date are, Providence, in 1849; Springfield, Mass., about 1850; Fall River, 1858; Lawrence and Lowell, 1857; Pittsburg, in 1856 and probably earlier; San Francisco, in 1856; St. Louis, in 1859; and Chicago, in 1862. In 1860 there were at least fifteen cities where evening schools had been conducted as part of the public school system. Nearly all the larger cities were familiar with the idea of such schools and of the use of public money for their support.

*Evening High Schools.*—While the first movement for evening schools was toward

giving those who lacked the rudiments of education the opportunity of acquiring them, there was very early manifested in some cities a tendency in the direction of affording means of further education to those who were studiously inclined and ambitious to improve themselves. The earliest indication of this was in Cincinnati, Ohio. As early as 1828 the Ohio Mechanics' Institute conducted lectures and classes in botany, chemistry, mechanics, geometry, and arithmetic. Apprentices and minors, sons of members, were entitled to attend these classes on payment of fifty cents per annum. This was a school of science, not a high school, was not free, and was restricted to a certain class of people, but it exerted a strong influence on the establishment of an evening high school. In 1841, and possibly earlier, the trustees of Woodward College and high school, then a private endowed institution, conducted evening classes in the college rooms, in which were taught "mercantile arithmetic, bookkeeping, algebra, geometry, architectural drawing, plane trigonometry with its applications, surveying, mensuration of planes and solids—particularly of carpenters', painters', masons', and bricklayers' work, etc." These classes were organized for young men who were at work during the day. This college or academy was, in 1851, merged into the public school system as the Woodward High School. The first evening high school in the country, conducted by the public school authorities, was opened October, 1856, in Cincinnati, and was undoubtedly the direct outgrowth of the two schools previously mentioned. In this school a preliminary examination in elementary subjects was required and a three-year course laid out. The first year there were 108 in attendance, all in the lowest class, besides some others in a preparatory class. The studies pursued in the lowest class were algebra, geometry, bookkeeping, drawing and design, and vocal music. The first public high school of any kind to be established in New York City was the evening high school, which was opened in 1866. This school was successful from its opening, and has had a continuous existence. In 1877 the number examined for admission was about 3500, and the number passed about 1800. No other evening high school was opened in New York City until 1887. An evening high school was first opened in Chicago in 1868. The same year the O'Fallon Polytechnic Institute was established in St. Louis. This was an evening high school, but with emphasis upon practical training. The same might be said of the Artisans' Night School, opened in Philadelphia in 1869. It included in its curriculum mechanical and engineering drawing and steam engineering, as well as geometry, physics, and chemistry. It was gradually changed by the elective system into an ordinary high school,

and in 1898 its name was changed to the Evening High School. Boston established an evening high school in 1870. There were, then, in 1870, at least five public evening high schools. These schools were not all of the same grade, the variation being much greater than in the day high schools. Some gave very elementary work, while some few were and are real high schools recognized as on a par with the day high schools, organized in courses leading to a diploma. In the majority of these schools there is a distinct tendency toward the more practical subjects, although the studies included in the curriculum of the day high schools are not neglected.

The usual time given to evening school work in this country is two hours per evening for four evenings a week, and twenty weeks a year, but this time varies greatly in different cities. One of the greatest difficulties is irregular attendance, the per cent of attendance on total enrollment ranging from twenty to sixty, or a little over. Various methods have been tried to counteract this. One that has been tried and has been very successful is that of charging a nominal tuition fee, \$1 or more a term. This is refunded at the end of the term in case a certain per cent of attendance is reached. The majority of teachers in the evening schools are day school teachers, but there is an increasing demand for specially trained teachers for this work, for it is coming to be realized that it takes a different type of teacher to do the best work in the evening school.

*Classes of Pupils Reached.*—(1) Those who are deficient in the rudiments, or who have not had an education equivalent to that of our elementary schools. Probably fully eighty-five per cent of the total number of the pupils are of this class. This class is composed of native Americans and of foreigners. Among the foreigners two classes are distinctly marked off: the illiterates, who not only do not know English, but have had practically no education at all, and those who are more or less educated. Many of the latter have received a liberal education in their own country, but on account of inability to speak and write English are at a great disadvantage. In the large cities, which receive such large numbers of immigrants, the per cent of foreigners in the evening schools is very large, while in other cities it is much smaller than the per cent of native Americans. (2) The second class found in the evening schools is made up of those young people who have passed through the elementary grades and some even partly through the high school, and who wish to complete their education. The needs of this class are as varied as their occupations. Some wish to prepare for entrance to college or university. The greater part, however, wish to prepare themselves for higher positions, for greater efficiency in the occupations in which they are engaged. From these has come an increasing demand for technical

## EVENING SCHOOLS

## EVERETT, EDWARD

and trade work, and it is very largely this class which is found in our few evening trade and technical high schools. (3) Another class, more or less distinct from the last, consists of men in business who wish help along special lines. There are very few opportunities for such training in our public evening schools. The Evening School of Trades, in Springfield, Mass., meets this need, in a way, and sometimes the classes of the Y.M.C.A. in a few cities.

*Attendance and Enrollment.*—Thirty-two cities reported evening schools in 1881, 165 in 1900, and 233 in 1909. The total enrollment in the cities reporting was 150,770 in 1890, 203,000 in 1901, and 379,052 in 1909. In the five years from 1904 to 1909 the total enrollment increased forty per cent. These figures include only those reporting to the United States Bureau of Education. It is probable that the enrollment is larger than this, for all do not report. In 1904 there were thirty-two cities reporting evening high schools, and the enrollment was 40,568. In 1909, seventy-six cities reported evening high schools, and the total enrollment was 75,342. In spite of the great increase in the enrollment in the evening schools, and their gratifying development, they yet reach but a small part of the young people under twenty-one who are not in schools of any kind. In 1907 a careful estimate was made of the young people between the ages of fourteen and twenty who were enrolled in schools of any kind. The data obtainable were by no means accurate, and the figures are subject to many inaccuracies, but it is the best estimate that there is, and probably indicates quite accurately the general educational situation in the cities of 25,000 inhabitants and over to-day. This estimate is found in Bulletin No. 1, 1907, of the Bureau of Education, p. 29. The number of pupils at each age is expressed as the per cent of the total number of young people fourteen years old.

PERCENTAGE OF SCHOOL ENROLLMENT, BASED ON THE TOTAL NUMBER OF CHILDREN 14 YEARS OLD.

Normal schools, colleges, universities, and professional schools . . . . .				0.5	1.5	2.0	3.0
Public evening schools Y.M.C.A. and Y. W. C. A. classes . . . . .	4.37	6.17	5.49	3.34	2.84	2.84	1.73
Total percentages	83.77	57.65	39.64	23.84	14.74	9.99	6.93

According to these statistics, it appears that, taking the total number of young people between the ages of fourteen and twenty, 66.21 per cent are not in schools of any kind. At the different ages this appears as follows: At fourteen years old, 16.23 per cent are not in school; at fifteen years, 42.35 per cent; at

sixteen, 60.36 per cent; at seventeen, 76.16 per cent; at eighteen, 85.26 per cent; at nineteen, 90.01 per cent; at twenty, 93.07 per cent. It can thus be readily seen that the evening schools are not beginning to meet the needs of the young people who can profit by such work.

**EVIDENCE.** -- What from the deductive point of view is called proof, or demonstration, is, from the inductive side, evidence and its interpretation. Proof consists in showing that a certain proposition or belief follows from principles which are independently accepted. Hence the question ultimately comes back to question upon what the principles themselves rest. Either they are assumed as self-evident or axiomatic, or they rest upon certain supporting facts as their evidence or ground of acceptance. Each branch of belief and science has of course its own distinctive type of evidence -- that is, of concrete facts that are adduced in support of its conclusions. From a logical point of view, the essential thing about a power of good judgment is that (1) it is aware of the sort of evidence required in a given field; (2) is skilled in selecting among facts or in sifting material so as to decide which is good evidence and what not; (3) and apt in using the material selected, in interpreting it as bearing upon any suggested principle. In practical and social matters, persons are confronted with complex situations, not with abstract principles, so that the essential thing in dealing with them is to be able to select, weigh, and use evidential material. Hence one of the most serious objections to an exclusively deductive method of teaching is that it affords no education fitting individuals to cope with the concrete situations of life. The same holds good, of course, in even greater measure, with methods of instruction that depend mainly upon dictation, learning by rote, or implicit reliance upon dogmatic rules. J. D.

**EVOLUTION.** -- **THE PHILOSOPHICAL CONCEPTS.** -- As a philosophic and cosmological concept, the notion of evolution was first formulated by the "nature philosophers" of Greece receiving its most striking statement at the hands of Heraclitus, who regarded all nature as a scene of "becoming" according to a certain law of proportionate exchange, termed by him *logos*. Apparently no serious attempt was made to apply the conception to human

history and society beyond a few elementary moral aphorisms. The Socratic movement checked in many cases further fruitful development of the concept of evolution. Accepting the doctrine of some of the "nature philosophers" that nature itself is of change, Plato and Aristotle both insisted upon the necessity of the control of this flux by fixed laws in the interest of fixed ends as the absolute termini or limits of change. Plato conceived the interrelation of the fixed types and ends, called by him Ideas, to natural change loosely and vaguely enough to permit him to conceive of a radical social change through the control exercised by absolute and objective purposes. But this very looseness left him open to the charge (by Aristotle) of separating change or becoming and true being, and thereby destroying the very idea of development. Hence Aristotle interpreted the Platonic philosophy so as to treat every case of genuine existence, or individuality, as a cycle of development from potentiality to its full term of completion, or perfection, in actuality. In this way, Aristotle appeared to give change a positive worth denied to it by Plato; and even to make "development" his own fundamental category. It has thus been claimed by some modern philosophers that Aristotle not only expounded a philosophy of evolution, but the only satisfactory philosophy, since he found the meaning of developing change not in the cruder and earlier states (origins), but in the mature and later results (ends). This overlooks the fact, however, that Aristotle absolutely denied any evolution of forms, species, and ends, etc.; and that his so-called development has to do simply with *individual* cases of change which are purely cyclical (circular) in quality, starting at one end literally to reproduce existent individuals in which the type of perfected form is already embodied, and, at the other end, terminating in an achievement of the fixed form of species. In this way, Aristotle confined change within certain absolutely fixed limits; in providing fixed place and function for change he really gave the most effective aid to the formulation of the scholastic static philosophy of the universe and life.

The social and the scientific interests of the Renaissance centered in change. When motion was made the prime category of physical science, and reform and progress the chief aim of social endeavor, it was only a matter of time that evolution should become the dominant conception of philosophy. In the later eighteenth and early nineteenth centuries the conception was applied in social and intellectual matters by Herder, Goethe, and Hegel, and by Condorcet and some of the French Encyclopedists. About the same time in the middle of the nineteenth century that Darwin and Wallace were applying the idea to animal and plant life, Herbert Spencer

attempted a universal synthesis on the basis of a generalized definition of evolution. In his own philosophy, however, he did not get beyond the notion of fixed cyclical recurrence of a chain of changes working between a fixed origin and fixed goal — evidence that his own thinking was never completely taken possession of by evolutionary conceptions. The influence of the concept of evolution upon the philosophy of education has been great, but indirect. As the general intellectual outlook of humanity becomes more dynamic, and the interest in novelty, variation of progress, correspondingly greater; and as faith grows in the genetic method as a method of intellectual analysis and definition, educational philosophy inevitably is influenced by the change.

Some of the concrete applications of evolutionary philosophy to educational concepts will be found under the captions ADAPTATION; ADJUSTMENT; CONFLICT; CONTROL; ENVIRONMENT; FUNCTION; HEREDITY; STIMULUS AND RESPONSE. J. D.

**EVOLUTION IN PSYCHOLOGY.** — In his discussions of the relation of biology to the science that deals with human life, Spencer raised the question whether there was any process of extra-organic evolution. The formulas which Spencer applied to human life are for the most part mere extensions of the formula of biological evolution. The general disposition in current psychological and sociological discussions is to accept Spencer's position and treat human life as a continuation of the process of biological evolution. Such terms as selection (*q.v.*), adaptation (*q.v.*), and variation (*q.v.*) are continually employed in sociological and even ethical discussions. In education the terms borrowed from biological science have frequently been employed to define the purpose and method of educational activity.

That there must be a clear recognition of some distinction, however, between human and animal life has frequently been suggested in scientific literature. Indeed, Darwin felt so keenly the importance of modifying the general formula of natural selection when applying it to human life that he wrote a volume on the *Descent of Man*. This volume substituted for the formula of natural selection, which Darwin developed in his *Origin of Species*, a formula of sexual selection or social selection. Later discussions of the same topic support even more fully the conclusion that we must work out a different view of the evolutionary process than that presented in animal biology in order to understand human life and human civilization. A frank recognition of the importance of consciousness suggests itself as the best solution of the difficulties thus recognized. With consciousness as a positive factor in human life there comes a type of selection and a type of control of the environment which has no parallel in animal evolution. Through mental

activity the human being has gained a complete mastery of his environment. He works upon it and modifies it, rather than fits himself to its demands. It is certainly true that human bodily organization has undergone no radical transformation and no adaptation to the physical world within historical times, or even within the period covered by our anthropological data. Man seems thus to have departed from the general type of evolution which appears in the animal kingdom, and to have a type of adaptation which does not require change in his bodily organs. Such a view of evolution as this creates a demand for a distinct psychological treatment of the problem of human evolution. C. H. J.

See ENVIRONMENT AND ORGANISM; GENETIC METHOD; SOCIAL PSYCHOLOGY.

**Scientific Theory of Evolution.** — The concept of evolution has been found useful, and, indeed, necessary in almost every phase of scientific inquiry. We have, therefore, almost as many sorts of evolution as there are departments of science. Evolution may be cosmic, chemical, geological, organic, psychical, or social; and special phases of each of these fields of thought have their own laws, which are, often enough, laws of evolution. Thus there are intellectual evolution, moral evolution, economic, political, linguistic, artistic evolution, and so on. Herbert Spencer has formulated the law of evolution as follows: "Evolution is an integration of matter and concomitant dissipation of motion, during which the matter passes from an indefinite, incoherent homogeneity to a definite, coherent heterogeneity; and during which the retained motion undergoes a parallel transformation." The operation of this principle Spencer endeavors to find in the sidereal and solar systems, in geologic history, in the history of organisms, of social organization, of language, of science, of the industrial and aesthetic arts, etc.

The concept of cosmic evolution was used by the Greek philosophers, many of whom conceived of æons of time, during each of which a cosmos such as we know evolved from some primitive element and again was resolved into that element. Anaximander (611-547 B.C.) held this primitive element to be undifferentiated matter, chaos; Heraclitus (495-435 B.C.) thought of it as fire. In modern times the nebular hypothesis of Laplace and Kant has afforded the principal notion of cosmic evolution. According to it the solar system has emerged from a fiery mass of tenuous particles, and various sidereal systems and nebulae illustrate different phases in this process, which is thus conceived as universal.

The concept of chemical evolution also is found among Greek philosophers. In general, they may be divided into two groups. One of these held that the various substances could all be transmuted into each other. Earth

could become successively water, air, fire, and perhaps ether. Democritus (*f. c.* 450 B.C.) arrived at the notion that the differences between substances could be reduced to differences in the form and size of their constituent atoms. Hence a change in form or size must involve a transformation of the substance. Others, like Anaximander, Empedocles (495-435 B.C.), and Anaxagoras (500-428 B.C.) held that the primitive elements could not be transformed into each other. Hence to them the process of chemical evolution was one of compounding and separating the original substances. Modern chemistry has followed this conception until recent years. The chemists have reduced the substances to elements, at present about seventy in number, and the innumerable compounds of these. The discoveries of certain periodic relations among elements and of radioactivity have, however, led many modern chemists to the belief that elements suffer transformation and may pass into each other. Thus chemical evolution becomes not merely a process of compounding and resolving elements, but of the actual change, decay, and transmutation of elements themselves.

The idea of geological evolution was familiar to the ancients. The theories of a primitive fiery state and of an earlier condition in which the world was covered with water, from which land surfaces later appeared, were common among them. Xenophanes (576-480 B.C.) identified fossils as the relics of former life, and argued from the presence of the fossils of marine animals upon mountains that they had formerly been covered by water. Avicenna, an Arabian philosopher of the tenth century, regarded mountains as either the effect of violent upheavals of the earth's crust, as by earthquakes, etc., or of erosion by water, or, perhaps, both forces. The earlier geologists were divided into the cataclysmic school, who believed that the various features of the earth's surface arose from violent cataclysms, and the uniformitarians, who held that they were produced by the action of causes found in operation to-day. Lyell may be regarded as the one who brought about the definite adoption of the uniformitarian point of view. The development of the concept of geological time was of immense value in furthering the employment of the general notion of evolution.

It is in reference to the history of organisms that the concept of evolution finds special application. For evolution is thought to mean progress, and while the transformations of the inorganic world are not in themselves betterments, the changes in the history of life have brought about what is recognized to be extraordinary advance. Indeed, the word "evolution" was first used by Bonnet (1720-1793) to indicate the development to a perfect form of that which is contained in a living germ. Among the Greeks the idea that the forms of

life change and improve was well known. Thales and Anaximander held that life arose from the slime of the sea. The latter believed distinctly in abiogenesis, or the theory that life arose from the inorganic world, a view discredited to-day. Empedocles held that the forms of life thus arising from the earth were in great variety, and that those imperfectly adapted were exterminated, leaving the perfect forms. Thus we have a "survival of the fittest." There is no evidence, however, to convince us that Empedocles believed one species to be transformed into another by this process. The fixity of species was also maintained by Aristotle, who opposed to the conception of a chance origin of the forms of life and the survival of the better adapted ones the notion of the struggle of each individual to express perfectly the form of the species which was implanted in it. Such a struggle, he thought, explains development or evolution, which he, therefore, interpreted as orthogenetic rather than as dependent upon chance variation.

Modern study of organisms was at first under the dominance of the idea that species were fixed. Such seems to be the notion of Linnaeus (1707-1778), although at times he suggests the possibility of transformation in particular cases. On the other hand, Buffon (1709-1788) inclines toward the notion of the gradual transformation of species through the influence of environment upon them. Among philosophers in the eighteenth century the idea of organic evolution became quite common, although the conservative forces of society were all on the side of special creation and fixity of species, a view supported not only by religious tradition but also by the great authority of Cuvier. Erasmus Darwin (1731-1802) and especially Lamarck (1744-1829) believed in organic evolution through the effects of use and disuse. In the early part of the nineteenth century the idea of the evolution of species through the natural selection of such chance variations as made for better adaptation was suggested by several naturalists, but it remained for Charles Darwin (1809-1882) to accumulate such a mass of evidence as ultimately to convince the scientific world of the existence of such a process. Darwin admitted the influence of the effects of use and disuse as a factor in evolution. Since his time several schools have arisen. The Neo-Darwinians, of whom the leaders are Weismann, Wallace, and Galton, deny the inheritance of the effects of use, and hence, on their view, the Lamarckian factor does not affect the evolution of species. The Neo-Lamarckians maintain the inheritance of acquired characteristics as a prime cause of evolution. (See ACQUIRED CHARACTERISTICS.) In recent years the possibility of evolution through the natural selection of chance variations has been questioned. The idea that it is through radical

variations (mutations), such as produce at once new types (heterogenesis), has been advanced by some, notably De Vries. Others have revived in various ways the notion of orthogenesis held by Aristotle, although as a rule they have disclaimed the thought of a directing form embodied in the evolving species (preformation), and have maintained the opposed view of epigenesis. (See HEREDITY.)

When we come to social evolution, we find that only in modern times has the concept been extensively applied. Aristotle outlined certain evolutionary phases of the history of political forms. The enlightenment of the eighteenth century, although it began with a revolutionary repudiation of the past, came ultimately to regard all history as progress toward a higher mental, moral, and social condition. Here the German thinkers, Lessing, Herder, and Hegel, are especially important. Lessing finds the development of culture to be the necessary order in God's education of the human race. He also introduces the idea of evolution in art forms, a concept developed much further by Winckelmann and Hegel. Herder writes a philosophy of history, showing therein a constant evolution of higher social and political forms, not only within separate nations, but from nation to nation. Hegel finds the same evolution in the relation of the concepts of the mind, and hence holds it to be inevitable in the history of thought, and in all the products of nature and civilization. Comte reacts against German rationalism, and divides human evolution into the three stages of the theological, the metaphysical, and the positive or scientific and empirical. Yet he sees a necessary evolution from one to the other, and also in the development of the sciences, and, indeed, in all human phenomena. His influence is great upon the English evolutionists, especially Spencer. Huxley has pointed out the conflict between evolution by natural selection and human moral ideals. David Starr Jordan and Sir E. Ray Lankester have shown how in society with its artificial conditions we may get not progress, but rather degeneration as the result of the selective effects of war, new forms of disease, etc. John Fiske and Joseph LeComte have striven to show that there is no essential conflict between evolution and religious faith. E. N. H.

For statement of Darwin's formulation of the theory of evolution, see DARWIN, CHARLES; for other aspects of the subject, see HEREDITY; SELECTION; also ADAPTATION; ENVIRONMENT.

**EWART, WILLIAM** (1798-1869).—A prominent English politician, educated at Eton and Cambridge, who devoted much attention to movements for social advancement and education. He was active in the movement for ameliorating the severe punishment for minor crimes. In 1835 he moved for the appointment of a school committee "to enquire into the best means of extending a knowledge of the fine arts and of the principles of design among the people—especially the manufacturing population of the country." The report of the committee led to the establishment of a School of Design at Somerset House in 1837, and ultimately to the Department of Science and Art. In 1837 Ewart advocated the opening of museums and galleries to the working classes. In 1845 he moved "that a statement be made on the part of the government of the condition and prospect of such educational establishments as were supported wholly or partially by a vote of this House," and "that it is expedient that schools for training of masters be more extensively promoted." Perhaps the chief service of Ewart was the passing of the Bill for enabling Town Councils to establish Public Libraries and Museums (1850). He also took an interest in the establishment of examinations for entrance into the civil, army, and diplomatic services, and in opening up facilities for the higher education of dissenters.

**EWING COLLEGE, EWING, ILL.**—A coeducational institution founded as the Ewing High School in 1867. The collegiate department was added in 1874, and the institution was placed under the auspices of the Baptists in 1877. Academic, collegiate, normal, fine arts, domestic science, and summer school departments are maintained. Candidates are admitted on an examination or upon certificates from accredited schools. The faculty consists of sixteen members.

**EWING, JOHN** (1732-1802).—The first president of the University of Pennsylvania, graduated at Princeton in 1752. He served as tutor at Princeton, founded the academy at Newark, Del., and was the first president of the University of Pennsylvania (1779-1802). He was one of the founders of the American Philosophical Society (*q.v.*) and the author of a *Natural Philosophy*. W. S. M.

**EXAMINATION OF PUPILS.**—See GRADING AND PROMOTION.

**EXAMINATION OF SCHOOLS.** — See ACCREDITED SCHOOLS; SCHOOL ADMINISTRATION; SUPERINTENDENT OF SCHOOLS.

**EXAMINATION OF TEACHERS.** — See CERTIFICATION OF TEACHERS; EXAMINERS, BOARDS OF.

**EXAMINATIONS.** — A term used to denote the method of testing educational progress, measured either by amount of knowledge acquired or by general intellectual capacity or ability. Such a method has been applied in all grades of education in one form or another. The earliest type of examination which prevailed was oral, either in the form of question and answer (cf. the textbook of Ælfrie (*q.v.*), which would lend itself to such a method) or of disputations (*q.v.*). Disputation, determination, defense of a thesis, or the delivery of a public lecture, provided other requirements such as payment of fees, residence, and attendance at lectures were satisfied, are forms which examinations took at the medieval universities (*q.v.*); (for details and differences at various universities, see also DEGREES). The written examination was unknown at the universities probably until 1702, when it was introduced by Bentley at Trinity College, Cambridge. Practical examinations had been employed for a long time in the medieval universities in such a subject as medicine. But the examination in its modern form is a development of the eighteenth century. The first honors examination, the earliest examination in the modern sense, was the Mathematical Tripos, founded in 1747. The qualification for a degree was in fact merely four years' residence. Those who worked did so at their pleasure; for those who would work there were, even in the worst times, adequate lectures. The first Tripos introduced a new order of things, but until 1797 the proctors added any names they liked to the list. In 1772 the Master of St. John's College, Cambridge, established examinations in his college (Graham Balfour, *Educational Systems*). The lead was taken up by Oxford in the famous "Oriel" revival. Before the end of the century examinations were introduced into Christ Church by Cyril Jackson, and in 1795 Oriel College began to elect to its fellowship from outside solely on the results of its own examinations. Oxford now progressed more rapidly than Cambridge. In 1802 a genuine examination for the B.A. degree was begun and a small honors list with the names in the order of merit was published. Between 1802 and 1870 there was an examination for the M.A. degree, but this never became effective, and there is not to this day any examination for the master's degree at Oxford or Cambridge. "In 1829 the Master and Fellows of Balliol began to elect scholars after examination. . . . The most brilliant success attended these reforms, and

encouraged similar measures elsewhere" (Balfour). Meantime in 1824 Cambridge had founded the Classical Tripos, though until 1850 it was only open to those who had passed in the Mathematical Tripos. The Moral Science Tripos and the Natural Science Tripos followed in 1851. In 1850 Oxford reorganized her examinations "and introduced Moderations as a test of pure scholarship in the middle of the University course." From this time forward new schools and triposes were created in rapid succession at Oxford and Cambridge.

A second development of examinations was to test ability to enter the professions, for which up to the nineteenth century preparation through a period of apprenticeship had prevailed. While many of the old professional societies have remained unchanged, the method of admission has been changed to an examination basis. For details see articles on ACCOUNTANCY EDUCATION; LAW, EDUCATION IN; MEDICAL AND SURGICAL EDUCATION; MINISTRY, EDUCATION OF; PHARMACEUTICAL EDUCATION; TEACHERS, TRAINING OF; also treated under articles on the separate national systems, *e.g.* FRANCE, EDUCATION IN; GERMANY, EDUCATION IN, etc.

Examinations mentioned up to this point have been qualifying tests to ascertain whether a candidate has reached a definite standard. A further extension of this is the competitive examination by which candidates are not only required to attain a standard, but are arranged in order of merit, on the basis of which rewards prizes, scholarships, or appointments are awarded. The most common use of this type of examination is to fill positions in government or municipal service. Civil service examinations, however, have been established comparatively within recent years in most countries. (See further PUBLIC SERVICE, EDUCATION FOR.) The competitive system is also used in most countries to secure places in the government institutions which prepare for the respective armies and navies. (See MILITARY EDUCATION; NAVAL EDUCATION.) Scholarships (*q.v.*), exhibitions (*q.v.*), fellowships, and other academic prizes are also awarded by some form of competition.

But it has always been in connection with the work of the school that examinations have been most frequently employed. Here they may be used periodically as part of the classroom routine to test the amount of knowledge retained by the pupil in a certain field (see REVIEW EXAMINATIONS), or at stated intervals to test the ability of pupils to proceed to more advanced work (see GRADING AND PROMOTION). In both cases, however, the work of examining is entrusted in most instances to the teacher who has charge of the class, or else is conducted by the principal of the school, when the examination is as much a test of the teacher as of the pupils. Examinations conducted by external bodies have been employed for various

purposes, (1) by state authorities to test the quality of work done by schools as a basis for the payment of grants. This pernicious system prevailed in English elementary education for many years, and is still the basis of payment in Ireland for secondary education. (See APPORTIONMENT OF FUNDS; (2) by state or other authorities, *e.g.* universities, professional associations, etc., as a test of the ability of pupils who are leaving the secondary school, to enter on higher studies or merely as a test of the knowledge already acquired. Under this type of examinations come the college entrance examinations (*q.v.*), school-leaving examinations, as for example the *Abiturientenprüfung* (*q.v.*, and GERMANY, EDUCATION IX), and the baccalaureate (see FRANCE, EDUCATION IX). Below a statement is given of the different examining bodies in England. In the United States there is a tendency at present to supersede such entrance examinations by a system of accrediting (*q.v.*), first introduced by the University of Michigan in 1871. (See COLLEGE ENTRANCE BOARDS; COLLEGE REQUIREMENTS FOR ADMISSION.)

In Germany and America the tendency has been to limit the number of examinations so far as possible, and by building up a strong teaching profession and system of inspection to accept the decision of the teacher on the question whether pupils have attained required standards or not. In France every step in the educational progress is marked by some form of state examination. In England a system of inspection and better trained teachers has taken the place of examinations in elementary schools. But in secondary education a multiplicity of examining bodies still remains, and since England is typical of an extensive system of examinations, this is described below in some detail.

**English System of School Examinations.**—The beginning of the method of examination, as we now understand the term, was in the sixteenth and seventeenth centuries, and is most clearly to be traced in the records of the Merchant Taylors' School, London. This school was founded in 1561, and in 1562 the first examination was held. It was a "solemn visitation" of the diocesan. Bishop Grindal and other learned men came to the school to examine "first the ushers and afterwards the forms." The ushers were questioned each as to his learning and his manner of teaching. Then the boys were questioned, form by form. The headmaster was Richard Mulcaster (*q.v.*), and the report of the examiners was commendatory, on the whole, the only reserve being that the staff, being northern men born, had not taught the children to speak distinctly, but that some of the boys showed attainments equal to those of any school in the realm, "which gratifying intelligence was quickly conveyed to Mulcaster, then lying sick, and was received by him with cheerful-

ness and gratitude." In 1564 Grindal again appeared, accompanied by Dean Nowell and other learned men. A boy named King gave before them a pithy and eloquent oration. Other boys presented verses, and then began the appositions of the chief four forms and an examination of the three ushers. The proceedings lasted from eight in the morning till five in the afternoon, with an interval for "a repast." These visitations or examinations were made usually once a year. In 1572 there appeared the Bishop of Winchester with Dean Nowell and again "other learned men," and the examination was more searching and comprehensive than hitherto. Before a considerable gathering of "venerable" men "the head scholars of the school presented themselves for examination; and after one had briefly enumerated the several books they were learning in Latin, Greek, and Hebrew, Nowell began the examination by directing the lowest of that form to declare the sense and construction of a particular ode of Horace, which from one to another he prosecuted through the whole number, until the captain, requiring diversity of phrases and variety of words and finally omitting nothing which might seem needful for the trial of their learning in the Latin tongue. After him Watts (Archbishop of Middlesex) examined the same boys in Homer as to their skill in Greek, which was his favourite language, and then Horne tried them in the Hebrew Psalter. In all which exercises, they were well allowed." Dean Goodman (founder of the Ruthven Free School, 1595) then examined the next form in Cicero's *Tusculan Disputations*. It was customary to elect, from the knowledge shown by the scholars on these occasions, scholars for St. John's College, Oxford. In 1586, Mulcaster resigned the headmastership, but in 1602 he again appeared at Merchant Taylors' School but, as one of the examiners assisting Dean (afterwards Bishop) Lancelot Andrewes, and took part in the "appositions." Then the four principal scholars pronounced orations, the captain and the second scholar in Greek, the third and fourth scholars in Latin. Mr. Gwyn (Doctor of Physic), one of the examiners, made a learned answer to the captain's oration. Sixteen of the principal scholars were then examined and a theme given them to write whilst the examiners went to dinner. Three scholars were then chosen for St. John's College, Oxford. In 1601, after forty years' work, the school statutes were revised and it was decided to recommend a "probation" of the school three times a year. This probation was to be made by the master. The testing was to last a day from half-past six in the morning till eleven, and from 12.30 till five o'clock in the afternoon. All forms were to be examined in writing. Precautions were to be taken against prompting and copying. No dialogue, epistle, theme, sentence, or verse was to be set twice in the

same year. Ample time was to be given to all. But failure to do the exercises well (by any negligence or lack of ability) for these probationations was to result in dismissal. A register of the school's probation was to be kept, in it to be entered the name of each boy in each of the six forms, length of stay in the school, what books he had read and how far in them he had read, and a record of his exercises. A comparison was thus to be made, and a permanent record kept, of progress from Probation Day to Probation Day. The master and his three teachers were to receive 6s. 8d. each for their work in examining.

The governors of the "greatest school in England under one roof" committed the examination to the masters "without any association" with them of outside examiners; first, because of their assured confidence in them; secondly, because the presence of strangers would hinder boys; thirdly, because, if a strange assembly were present, they would take off the master's attention as well as distract the minds of the boys. Thus the Visitation (*q.v.*) of the school by the Diocesan led first to oral examination by the bishop and other learned men, then to the probation by the headmaster and teachers themselves, to be reviewed by the bishop or visitor and the Court of Governors and their friends. The examinations were the prelude to the choice of scholars for the university. With the visiting of the examiners and the governors, there sprang up the idea of a school show day, the Declamation Day, as it was often called, to which governors, parents, and those interested in the school, either magnates or the public, came that all might rejoice together in the performances of the pupils. It will be seen that the plan of probation at Merchant Taylors' School embodies examinational ideas for which reformers have still to plead to-day: confidence in the masters to conduct their own examinations, a style of examination devised to bring out active and initiative powers of pupils even more than to test mere retentive capacity, and the work required in examination to be qualitative rather than quantitative. This latter feature is the more noticeable, seeing that the curricula of the schools in classics was so extensive. Perhaps the most remarkable point in the Merchant Taylors' scheme is the inclusion of the register of the school's probation. It is not improbable that this plan has the future with it. For it is a recognition of comparison not only of pupil with pupil, but of the ability of a pupil at one probation with his ability at the next and following probationations. It is thus often material for considering the progress of ability as well as the attainment of a standard of knowledge. It shows the power of using knowledge at entrance, and all along the line of the pupils' course, three times a year, and is an indication of educational process in the individual, in-

stead of being mainly concerned with competitive merit and relative position in an order of merit according to some objective standard of attainment.

Examinations of school were required by the statutes of St. Saviour's Grammar School, 1562, Tonbridge, 1564, Oundle School, 1566, St. Albans, 1570, Sandwich, 1580, and Codwell (Herefordshire), 1612. The system was therefore established in schools by the time of the sailing of the Pilgrim Fathers.

It was not until the second half of the nineteenth century that the examination system which marks English education received its fullest development, until at the present day the multiplication of examinations and examining bodies has given rise to a situation which is leading to a reconsideration and reform of the system. But whatever arguments may be adduced in favor of or against examinations, thus much may be said by way of preface, that English education could never have reached the present stage of development without the influence of the system, pernicious and exaggerated as that may have been. Both in elementary and secondary education the examinations helped to standardize schools and curricula; they introduced new branches of study, and kept teachers, who would otherwise have been inefficient, to certain easily formulated and definite standards, however faulty and objectionable these may be in the light of later educational theory.

Elementary education was submitted to the controlling influence of examinations by the action of the Rt. Hon. Robert Lowe, who in 1861 introduced payments by results as the most mechanical and ready method of measuring efficiency. All children over six years of age in the elementary schools were to be examined individually once a year in the three R's, standards being arranged according to age. Government grants were paid according to the results and tendencies. A minimum of education was thus secured to children of all abilities, but a monotonous uniformity was introduced. Teachers were not only stimulated by the prospects of the grant, but were placed at the mercy of local managers to whom the grants were directly paid. The system made every pupil rote perfect in the three R's. One inspector even went so far as to say that "the studies of the classroom must be those wherein progress can be definitely measured by examinations." Another inspector, in dictating out of a reader which had been used by the school, changed some of the words, but found on marking the papers that the pupils had not noticed his changes, and evidently had learned the book by heart. Great care was taken by managers and teachers to make a good showing on the day of inspection; the premises received vigorous cleaning, and the children were strongly urged to appear with clean hands and faces and in their best clothes.

The system did not continue without considerable opposition from those interested in education. Matthew Arnold (*q.v.*), himself an inspector, reports "That the mode of teaching in the primary schools has fallen off in intelligence, spirit and inventiveness," owing to the introduction of the mechanical processes. Slight modifications were made in the system; the amounts of the grants were altered; additional grants were given for "specific subjects" (geography, history, algebra, geometry, and any other scheme of work approved by the inspector); examinations of Standards I and II were abolished in 1873 and 1874. The Royal Education Commission of 1886-1888 recognized that some doubt was expressed whether the system of examinations fosters a healthy feeling, and was inclined to believe that overpressure both of teachers and pupils was caused. The majority held that "so long as a money value is attached to each success in the individual examination of the children attending any elementary school, and so long as the teachers are dependent on the grant for part of their income, there is great risk that teachers, in considering their own reputation and emoluments, may endanger the health and welfare of the children." In the same period an agitation was conducted in the press (see *Nineteenth Century*, November, 1888, and February, 1889) on the whole question of examinations, and Mr. Auberon Herbert published a collection of letters under the title *The Sacrifice of Education to Examination* (London, 1889). As a result individual examinations were abolished in 1890, and "examination by sample" was introduced, by which the inspectors could examine different parts of a class in different subjects. In 1895 inspectors could visit schools without previous notice. By 1897 the system of payment by results was abolished, and with it the system of wholesale examinations at the hands of the government.

A similar system of examinations and payment of grants on the results was employed by the Science and Art Department, which made payments to schools for pupils winning prizes; at first only six subjects were offered for examination, and this number was gradually raised to twenty-six. Elementary school teachers qualified themselves by obtaining the department certificate, and by teaching science subjects in the evening were able to secure the grant. The system encouraged the rise of schools of science and the teaching of science and art subjects in secondary schools. Payments by results were abolished by the Department in 1895.

In the two systems so far mentioned there was at any rate a certain amount of uniformity in standards of requirements and in organization. But it was in the field of secondary education that the tyranny of examinations and examining boards with different standards, requirements, organization, and dates was

felt. In 1853 the College of Preceptors (*q.v.*) began a system of examinations in secondary school subjects (Latin, French, English, history, mathematics, geography, drawing, some science, and Greek). The examination was open to both boys and girls, and certificates were given on the results. The examinations were held twice a year at local centers. In 1858 the Society of Arts, which in 1852 had formed a union of mechanics' institutes, proposed to hold examinations of persons over fifteen years of age on leaving school in mathematics, English, history, Latin, French, and German; in 1873 technological examinations were added, but were transferred in 1879 to the City and Guilds of London Institute. In 1858 Oxford undertook the examination of pupils in secondary schools through a body of delegates, and gave the degree of Associate of Arts to successful candidates; girls were admitted in 1870. Cambridge also instituted a system of examinations for boys only in 1858, and extended it to girls, who were allowed to take the papers in 1863, and in 1865 were placed on the same footing as boys. Preliminary sections for pupils under fourteen were also instituted. Centers were established not only all over Great Britain and Ireland, but also in the colonies. The two universities held their examinations at different times of the year. When in 1869 there seemed a possibility that a government examination would be established for secondary schools, as a result of the Endowed Schools Act, the headmasters at their conference in 1870 urged the universities to take up the work and to grant leaving certificates which would exempt from entrance examinations to the universities. The result was the establishment of the Oxford and Cambridge Schools Examination Board, or the Joint Board, in 1873. Girls were admitted to the examinations in 1878, and in 1882 a junior certificate examination was instituted. The papers were marked by the masters of the schools, and were reported on by the examiners. London University held its first examination in 1838, which included arithmetic and algebra, English history, geography, Greek, Latin, chemistry, natural history, geometry, and classical history. Students took first the pass papers and then honors. At first the examination was limited to students in affiliated colleges of the university, but in 1858 was thrown open. This examination continued to increase in difficulty, and complaints were heard from schools until the requirements were revised in 1898. When the University of London, by act of 1898, again became a teaching institution, the external examinations for external students were retained. Local examinations are also conducted by Durham, Birmingham, Manchester, Liverpool, Leeds, and Sheffield universities, the last four being combined as a Joint Matriculation Board. The University of Wales and the

Central Welsh Board also hold examinations for matriculation and leaving certificates. Other examining boards are the London Chamber of Commerce, the City and Guilds Technical College, and the Lancashire and Cheshire Institute, which are concerned mainly with examinations in technical and scientific subjects. This does not exhaust the list of examinations or examining bodies; Oxford and Cambridge in many cases insist on candidates passing either in whole or in part the Responsions and Previous Examinations, while their colleges may insist on an additional matriculation examination. Further, none of the above examinations usually count anything toward scholarships or prizes, nor toward the examinations for entrance into the training schools for the army and navy (Woolwich, Sandhurst, Osborne) or into the civil service. The different branches of the public services have their own entrance examinations, which have led to the establishment of numerous "crammering" institutions. One of the evils of the examinations for the lower branches of the civil service is that boys and girls tend to leave the regular secondary schools for the crammer.

It is only within recent years that exemptions have been accepted by professional bodies, by which a certificate of success in any of the recognized university examinations is accepted in lieu of their own preliminary examinations. But many of them still provide their own examinations. Among these may be mentioned: the Institute of Chartered Accountants; the Society of Incorporated Accountants and Auditors; the Institute of Actuaries; the Royal Institute of British Architects; the Institution of Civil Engineers; the Law Society; the General Medical Councils; the Pharmaceutical Society of Great Britain, etc.

The evils of overexamination are, however, beginning to be slowly recognized. In 1903 the Consultative Committee of the Board of Education recommended, after conferences with several associations representing teachers, the establishment of a representative central board to coordinate and control standard of examinations and to secure the interrecognition of certificates. (See Board of Education, *Circular*, July 12, 1904.) Inspection, both by universities and by the government, is gradually increasing in extent and importance. Universities are cooperating with each other and combining to reduce the multiplicity of entrance and preliminary examinations, and professional bodies are recognizing equivalents and granting exemptions in these. The external examinations and their attendant evils are supplemented by the number of examinations held within the schools by the teachers. Each term is concluded by an examination in all the work immediately preceding. Promotions from one class or form to another depend on the results of the term examination. In-

creasing attention, however, is being drawn to the importance of relying on the teachers' testimony on a pupil's work and on the pupil's record in the classroom rather than on the results of an examination, which may be vitiated through several causes.

The advantages and disadvantages of examinations have been frequently discussed, and several points stand out clearly. That they are hygienically harmful to the majority of pupils is shown in detail in the following article (EXAMINATIONS, HYGIENE OF). The limitations of the English system of elementary education were eloquent proof that examinations do not constitute a satisfactory basis for the distribution of money grants to schools, nor do they secure the results which are aimed at—general educational efficiency (see APPOINTMENT OF FUNDS). Examinations cannot provide the best kind of motives for study, and do not secure the proper type of interest in school work; the stimuli afforded are adventitious and artificial. Too many accidental conditions may enter into examinations which may counteract their value as tests. Further, an examination over a large area cannot be addressed to the individual. Frequently success in examinations may be due, not to innate general ability, but merely to retentive powers. Above all, external examinations disorganize school work and tend to limit the good teacher and to reduce all teaching to a dead level of uniformity, and in most cases must result in cramming. That the evils which follow in the train of competitive examinations for public service appointments are less harmful than the old system of nomination by political influence is obvious; but another question arises, whether national efficiency is secured by the present means. There is a tendency in England at present to introduce more widely a system of oral examinations such as has been employed recently by the Admiralty to secure officers for the navy, and by the West Riding Council in the award of scholarships. The whole question of whether success in examinations is followed by success in after-life is one that has never been submitted to scientific investigation.

F. W. AND I. L. K.

On the use of examinations as a classroom procedure for review, see REVIEW EXAMINATIONS; METHOD; RECITATION.

**EXAMINATIONS, HYGIENE OF.**—In recent years there has been a strong movement for the abolition, or at least the limitation, of school examinations on account of the many evils, hygienic and pedagogical, that seem to be inevitably connected with such tests. There seems to be, however, a fairly general consensus of opinion that examinations of some kind are necessary, and hence the hygienic aspects of the subject are of special importance.

Hygiene is concerned both with the direct results of examination in their bearing upon the health, and also with certain secondary and

indirect results of examination. The data in regard to the direct effect have accumulated in great abundance. Examinations are often the cause of overpressure, and serious physical disorder is not infrequently produced by the strain of preparation and of performance. Especially in England, Germany, and other European countries has this been the case. Studies in Russia, where examinations often extend over a period of several weeks, have shown loss of weight and other indications of physical strain in pupils at such periods. In Germany fear of examination has been found to be frequently one of the causes of suicide among school children.

In this country we have no results of special investigations concerning the effect of examination on the health of school children, but the reports of innumerable observers show that frequently there is dangerous nervous strain; and that even the best students often cram before examinations in an unhygienic manner will be hardly denied by any who are young enough to recall their own student days. In great universities in this country the writer has seen mature students of industrious habits become more or less abnormal, not to say pathological, in their mental activity on the eve of examination, and exhibit the phenomena of overfatigue during the examination itself. The pressure of examination is likely to fall hardest on those who least need the stimulus, and instances of overwork before examination are not rare among the best students. Considering the matter from the standpoint of psychology, such violent mental athletics are both wasteful and injurious. Modern psychology and psychiatry make plain the need of regularity in intellectual work and the danger of any kind of abnormal mental activity. The unnatural method of study on the part of the examinee of which the protestants in the *Nineteenth Century* complained is all too prevalent in this country. The evil here may be less in degree, but it is of the same kind.

There are, besides, certain secondary results of examination which are distinctly evil, as they tend to produce habits of unnatural and disorderly thinking. Some of these are illustrated by experimental studies that have been made in Germany. Lobsien has made interesting experiments on the psychology of school examinations. He wrote on a black-board twenty simple examples in arithmetic. Fifty-four boys of the age of eight were tested by him. The experiment was made twice. The test of normal conditions was similar to an ordinary study hour in arithmetic with silent reckoning. Before the beginning of the special test the children were told that their work would be considered as an examination and as the basis for their marks. The result was as follows: With the normal test there were 39 per cent of the examples wrong; with the special test 50 per cent. The effect of the ex-

amination was to cause confusion of association and error. Lobsien made also a similar test with dictation exercises. The results corroborated those of the first experiment. In all cases the examination injured the character of the performance, and especially in the case of the poor pupils. Lobsien extended this experiment also to the qualitative errors. The greatest number of errors, namely, 42.7 per cent, occurred in cases of words which came under definite rules. Plecher has more recently made experiments to test the results found by Lobsien, although without testing the character of the errors, and has found similar injurious results. Indications of emotional strain were also found. That these conditions of anxiety were actually present was proved by an experiment which Plecher performed with thirty-eight children twelve years of age in a class of *Scota* of the common school. Some days after the official examination at the close of the year, he had the pupils prepare a so-called free essay in regard to school examinations. Of thirty boys, twenty-nine testified to the presence of a feeling of anxiety, of course in the most varied forms of expression: "I do not trust myself to speak"; "I am glad of the examination, but when the *Herr Oberlehrer* comes, I am afraid"; "If I reckon, for example, two hours, I quite lose my senses." One pupil wrote, "If it is stated that we have an examination to-day, then a great dread comes over me, because I always think I shall do everything wrong. The thought always keeps working in me, and then with the best of will, I can do nothing. When we are through, then the anxiety no longer remains."

Equally bad, perhaps, are the habits of study fostered by preparation for examination. It is a mere commonplace to say that in many schools the best preparation for an examination is to have in memory a vast number of details. The student may enter the examination in such a condition of brain fatigue that he would find it difficult to solve a simple original problem; but if he have this plethoric memory of details he will succeed. A good memory, as Helvetius said, is a phenomenon of order. The normal mind, like the good householder, has its possessions stored away in various closets, drawers, and pigeonholes, or, in technical terms, in various association complexes; the student prepared for examination is like the unfortunate man who must move at a sudden alarm and has all his goods piled together at the street door ready for the truckman. Normally much of our knowledge is unconscious. Even what we cannot remember is not wholly lost. Ebbinghaus in his experiments in memorizing nonsense syllables found that even where the memory of a series of syllables was so evanescent that after an hour it could not be recalled, a certain hidden skill persisted unconsciously, so that the same series could be relearned, even after the inter-

## EXAMINATIONS

val of a month, in much less time than a new series. Forgetting is a normal function of the mind. We retain comparatively little that we have learned, except main principles and this unconscious element. The latter, however, is valuable. It is this that makes us feel at home in a subject. At the end of a college course a large part of one's acquisition is of this kind; the ordinary examination cannot gauge it, but puts a premium upon abnormal mental activity.

Hygiene requires that examinations should be given for the sake of the students, and not in behoof of an institutional standard. Apart from examinations at graduation and the like, the chief reason for formal tests is to determine a pupil's fitness for doing profitably a higher grade of work. When this can be determined without examination, a formal test is unnecessary.

The famous German educator, Professor Paulsen, has enumerated the rules which should govern examinations from a pedagogical point of view. There is an almost equally good code of rules from the point of view of hygiene for avoiding the evil secondary results of examination. They are in part as follows: "(a) Look for the positive acquisitions of the student. Examination as such has the opposite tendency—it gives prominence to the deficiencies. (b) Begin with easy, simple, definite questions. The missing of a question and answer in the beginning frequently confuses and upsets the whole affair. (c) Treat errors and blunders in accordance with Galatians vi, 1: 'Brethren, if a man be overtaken in a fault, ye which are spiritual restore such an one in the spirit of meekness, considering thyself lest thou also be tempted.' (d) Do not forget that for most men an examination does not afford a good opportunity to appear in a favorable light; for this reason subjoin, as occasion may require, *additis addendis*."

The special demands of hygiene in regard to examination may be summed up briefly and dogmatically as follows: (1) No formal written examination should be given in the school below the sixth grade. (2) Examinations below the high school should not be more than forty minutes in length, and in the high school they should not be more than one hour in length. In colleges, higher technical schools, and the like, no examination should last more than three hours. (3) Not more than one examination should be given on the same day in the public schools; and in the colleges and higher schools not more than one three-hour examination or two one-hour examinations should be given on the same day. (4) Periods of examination extending over several weeks, as in some European countries, should not be permitted. (5) The sanitary conditions of the examination room as regards adequate light, good ventilation, suitable temperature, and

## EXAMINERS

adequate humidity of the air should be always provided for. (6) Hygiene joins with pedagogy in emphasizing the advantages of examination questions which test ability and power of straightforward thinking over examinations that put a premium on cramming, *i.e.* original problems, translations at sight, the writing of original themes, and the like.

**EXAMINATIONS FOR TEACHER PROMOTION.**—See TEACHERS, PROMOTION OF.

**EXAMINATIONS, PUBLIC.**—See EXAMINATIONS; EXHIBITIONS, SCHOOL.

**EXAMINERS, BOARDS OF.**—State, county, and city boards of examiners exist in many places in the United States, for various purposes, such as the auditing of accounts, the approval of contracts for work performed, the inspection of public institutions, the ex-

amination of candidates for certificates to teach, etc. From an educational point of view boards of examiners mean only the latter two, and usually only the last. Boards of examiners for institutions are not found with any frequency, and only as boards of inspection for higher institutions and for a few city school systems. A board of educational examiners is appointed each year for West Point, Hampden Normal Institute, and a few state normal schools and eleemosynary institutions; and the boards of school visitors commonly appointed each year in the New England towns are forms of boards of examiners. The principle of inspection and approval by outside bodies is little used in the United States, the conduct of institutions being entrusted almost entirely to boards of trustees, governors, or regents (see **BOARDS OF CONTROL**) in the case of institutions, and to the boards of education, boards of school commissioners, or school committees in the case of our city systems. By the term "board of examiners" is usually meant boards which examine and certificate those who wish to become teachers in the public schools. Such boards are of three kinds, — state, county, and city or district.

**State Boards of Examiners.** — One of the best examples of this type is to be found in Alabama, where a State Board of Examiners has been constituted by law, consisting of the State Superintendent of Education, and four others appointed by him for four-year terms. This board prepares all questions for the examination of all teachers in the state; appoints persons to conduct examinations for them in each county, and to transmit the answer papers to the State Board of Examiners; examines and grades the papers of the applicants, and issues to those who pass teachers' certificates of three grades, the grade varying with the percentage made in the examination, and also life certificates to those who have proper qualifications; keeps a record of all certified teachers in the state; and may revoke any certificate for cause. Even graduates of the state normal schools must take the examinations. All certificates issued are valid to teach in any county in the state. A similar State Board of Examiners is to be found in Arizona and in Wyoming, except that in Wyoming the State Superintendent of Public Instruction is not a member of the examination board. In Connecticut, West Virginia, and a few other states the State Board of Education acts *ex officio* as a state board of examiners, the State Superintendent of Education doing most of the active work. In a number of states, as for example Indiana and Oregon, the State Board of Education acts as an examining body only for life diplomas or state professional certificates, or both, all other certification being left to the county or local school authorities. The tendency within recent years has been to increase the number

and the powers of such central certifying bodies.

**County Boards of Examination.** — In a large number of the states all county teachers' examinations are given by the county superintendent of schools, either using questions prepared by him or by the State Superintendent of Public Instruction, or by the State Board of Education; and then certificates to teach in the schools of the county, often of different grades and periods of validity, are issued by him. In ten states a special county board of examiners exists, and in about an equal number of states, mostly in the South and West, the county board of education acts *ex officio* as a county board of examiners. In either case it is customary for the board to prepare all questions, examine the candidates for teachers' certificates, grade the examination papers, grant the certificates to teach, and issue all certificates granted on the basis of credentials coming from other counties or states. Such boards are usually paid a *per diem* for their services, and the members appointed are usually successful teachers in the county.

**City Boards of Examination.** — In many states, particularly in the eastern part of the United States, the larger cities are permitted to examine and certificate their own teachers, independent of the county or state examining system or systems; and in other states the cities, while accepting the county or state certificates so far as they go, superimpose a city examination, usually of both a pedagogical and a personal nature, as a further test of fitness. To conduct these, special city boards of examination have usually been created, though in some cities the city superintendent of schools conducts the examination. In a few large cities, such as New York, special city boards of examination have been provided, the members of which devote most or all of their time to the work. In smaller cities, as for example Dayton or Jersey City, the city superintendent of schools and from two to four others, usually principals or teachers in the schools, examine all applicants and grant all city teachers' certificates. The additional members are sometimes appointed by the superintendent, more commonly by the board of education on the recommendation of the superintendent, and sometimes include one member of the board of education itself. In nearly all cases where separate city certificates are required they represent a higher standard of education and professional training and experience than do the regular county or state teachers' certificates. As state standards rise, the tendency is to dispense with the separate city test. In a few cities, as for example San Francisco and Los Angeles, the city accepts the state or county certificates at their face value, so far as they go, and then superimposes an additional educational and personal test, to enable it better to select teachers of larger capacity

and greater personal skill. In these cases the city board of examination consists of the superintendent and such persons engaged in educational work as may be designated to assist him in conducting the special city examinations.

**Town Certificates.** — In the towns of some of the New England states, as for example Massachusetts, the town certificate takes the place of the state or county certificate, found elsewhere. Here the town school committee (board of education) examines as well as employs all teachers. In the larger towns this passes over into a city board of examination, by the delegation of authority. E. P. C.

See CERTIFICATION OF TEACHERS, and the articles on state and city systems.

**EXAMPLE.** — In the teaching of arithmetic an "example" is a sample problem set by the teacher to illustrate the principles of mathematical calculation. More frequently the "example" is a typical exercise in which the pupil applies and drills his knowledge of arithmetic. In the current usage of teachers the "example" is frequently contrasted with the "problem," the distinction being that one is an abstract and symbolical statement of numerical facts, and the other a concrete and descriptive statement. The "example" is usually completely expressed in mathematical symbols, and the "problem" is commonly stated in words. The expression "clothed problem" (from the German) is occasionally used to mean what is here designated as "problem," and "abstract problem" is used to mean what is here designated as "example." In the case of the example, the mathematical sign tells the child what to do, whether to add, subtract, multiply, or divide; the "example" being a kind of prereasoned problem, the pupil has only to manipulate according to the sign, his whole attention throughout being focused on the formal calculation. In the second case, the child has two distinct functions: he must, from the description of the situation presented, decide through the process of reasoning what he is to do (add, subtract, divide, or multiply), and having rendered his judgment, he must proceed through the formal calculation.

As the "problem" involves two types of mental processes in a single exercise, and the "example" but one, the usual procedure in teaching is to take up the formal side through "examples" first, and, later on, the applied side through the use of problems. This means that the first emphasis is on formal and abstract work rather than on a treatment of natural, concrete situations, an emphasis not wholly sanctioned by modern psychology and the better teaching procedure of other subjects. The better practice, found particularly in the primary grades, is to begin new difficulties through a concrete, objective presentation of problems, then pass to the formal

work of the "example" and finally to a considerable use of the applied "example" or "problem." The abruptness of transition from objectified problems to the formal work implied in "examples" is broken by the use of "number stories" which are descriptions or narrations of easily imaginable situations or events.

See ARITHMETIC; PROBLEMS.

**EXCEPTIONAL CHILDREN.** — For a time there was a tendency to look upon exceptional children as being separated in a well defined way from normal children, and special educational procedures were provided for them. In recent years, however, closer analysis has shown that a very large number of children diverge more or less in particular respects from the normal, but not in a degree to deserve the designation "defective" or "abnormal." It is now a well recognized fact that in all schools a considerable number of children vary sufficiently from the normal to deserve special recognition and some form of special educational treatment. Courses of study and programs must naturally be devised for the large number who are normal in capacity and attainments. Such courses of study and programs, of necessity, fit more or less badly children who vary from the normal. A more efficient and sympathetic education is steadily endeavoring to discover and classify cases of educational misfit, and to produce forms of education suited to them.

Exceptional children present many different types of variation. Sometimes this is due to recognizable causes of a physiological nature; in other cases the differences spring from hidden sources, and manifest themselves as dullness, slow reaction time, incapacity for abstract thinking, precocity along special lines, and an unbalanced condition of certain instincts, like those of aggressiveness, concealment, and fear. No sufficient analysis has yet been made to show how far conditions of inheritance and conditions of environment are respectively responsible for the development, on the one hand, of exceptional characteristics, and on the other, for the suppression of certain normal tendencies.

In this connection, it should be noted that qualities which later make for extreme delinquency or defectiveness may, if dealt with in time, be adjusted; for example, special schools exist for the custody and training of delinquents; but a keener educational discrimination is now seeking prospective delinquents in their incipient stages, with a view to the early application of purposive measures. There is a widespread conviction that a more perfect knowledge of pedagogy would enable schools at an early stage to detect and educate to better advantage those who later become known as dullards, backward children, and abnormally precocious along special lines.

Under ordinary schoolroom conditions, the educational treatment of exceptional children is now being met in some measure by the provision of flexible grading and promotion (*q.v.*). Different groups of children are selected with a view to allowing them to make progress through the course of study at different rates; and, to some extent, the work may be modified for each group with a view to taking advantage of educational peculiarities. Again, some schools allow certain adjustments within the course of study itself by exempting exceptional children from requirements that may be appropriate for normal children. Subjects like grammar and the more advanced arithmetic requiring capacity for abstract thinking may be omitted, or deferred by certain pupils who seem incapable of good work in this direction; on the other hand, artistic or musical talent beyond the ordinary may be encouraged. Another device, proving effective with some exceptional children, is the provision of a large amount of concrete or practical work. There now seems little doubt that many so-called exceptional children are capable of considerable educational development from experience with tools and concrete materials. The truant schools of England are finding this industrial work an exceptionally useful medium for the development of certain types of children who vary from the normal. (See INDUSTRIAL EDUCATION.)

While probably many other developments suited to exceptional children will be introduced into courses and programs in such a way as not to involve any segregation of such children, it is important to note that special classes, ungraded classes, and more or less segregated schools are at the present time serving best to illustrate the needs and advantages of educational procedures adjusted to the needs of these children. Whenever a special group of children can be isolated, such as the unmanageable, the tuberculous, the crippled, the mentally defective, and those deficient in one or more of the special senses, it becomes a simple problem to evolve special educational means adapted to them. Where children similarly exceptional, but in a lesser degree, are retained with children pursuing the usual program, anything like individual consideration is difficult, and apt to be occasional. The same applies to children that, in one or more directions, present more rather than less of native or acquired capacity. It would appear, therefore, that current tendencies look to a further segregation, of a temporary nature, at least, of children requiring special treatment.

Systems of education, particularly in cities, have long tended toward a highly mechanical organization. Child study and a close consideration of educational results now constantly suggest flexibility and adaptation, and it becomes a problem of administration to

provide for educational adjustment of this sort, without incurring for the children the penalty of social segregation. The special education of the deaf has long been considered a necessity, but in Chicago schools the attempt is being made to carry on a part at least of this education where the unfortunate children may have the advantages of contact with those in full possession of their senses. Classes for crippled children may not be so far isolated that such children have no contact with those of normal development. The complete detachment of the delinquent or truant may produce some results more than offsetting the advantages of the special educational treatment given. It would appear that current tendencies are in the direction of the formation, to an increasing extent, of classes or other special opportunities for the development of the peculiar education most needed by exceptional children, on the one hand; and, on the other hand, the provision of means whereby, for purposes of social contact, such children may be kept in harmonious touch with the home, school, and street environments. Contemporary educational theory insists that education shall consider the individual; and the necessities of administration demand that, within limits, like individuals be gathered together. The broader educational view, however, recognizes that formal teaching is but one part of the education of exceptional children; the other part is to be found in the conservation, as far as practicable, of a normal environment suited to childhood. D. S.

Under the discussion of special forms for the education of exceptional children will be found such topics as: DEAF, EDUCATION OF THE; DEAF-BLIND, EDUCATION OF THE; BLIND, EDUCATION OF THE; BACKWARD PUPILS; IMMIGRATION AND EDUCATION; CRIPPLED CHILDREN, EDUCATION OF; NERVOUS CHILDREN, EDUCATION OF; SUPERNORMAL CHILDREN; TRUANCY AND DELINQUENCY; TUBERCULOUS CHILDREN, EDUCATION OF; SPEECH DEFECTS, EDUCATIONAL TREATMENT OF; OPEN-AIR SCHOOL; RETARDATION AND ELIMINATION OF PUPILS; SPECIAL CLASSES, etc.

**EXCEPTIONAL CLASSES, EDUCATION OF.**—See EXCEPTIONAL CHILDREN.

**EXCHANGE OF TEACHERS AND PROFESSORS.**—See INTERNATIONAL EXCHANGE OF TEACHERS AND PROFESSORS.

**EXCLUSION FROM SCHOOL.**—While exclusion from school must be determined with regard to law, hygiene makes certain demands, on the principle that what is necessary for the welfare of the school will ultimately

be sanctioned by the law. The causes for which exclusion is deemed necessary for the health of the school are chiefly the following: measles, scarlet fever, diphtheria, tonsilitis, whooping cough, mumps, chicken pox, pediculosis, septic inflammations with offensive odor, itch, and sometimes other skin diseases; the specially virulent diseases, such as syphilis, leprosy, and smallpox; in some cases tuberculosis, grippe, and colds; also certain nervous diseases and mental disorders, where there is danger of psychic contagion or serious interference with school work, such as epilepsy, chorea, hysteria, and certain extreme sex perversions; and, finally, most cases of feeble-mindedness.

In many of these cases exclusion from the school is unnecessary and unwise, if special classes can be provided for those afflicted. In cases of hysteria, for example, the discipline and care of the school is a great advantage; and in case of tuberculosis, where outdoor classes can be provided, the school is likely to be an aid in the care of the disease.

Sometimes it is necessary to exclude healthy pupils for the welfare of the school, notably cases of extreme moral delinquency and the carriers of disease. For example, whenever a case of diphtheria breaks out in a school, those pupils who are found by culture tests to be harboring the Klebs-Loeffler bacillus, the germ of diphtheria, should be excluded from the school. It is customary also to exclude the brothers and sisters of children who have contagious diseases. In all cases where healthy pupils must be excluded, special classes should be provided for them if possible.

In clear cases of diphtheria, scarlet fever, measles, and the like, the necessity for exclusion is obvious. In doubtful cases the question of exclusion should be decided by the school physician, or, where there is no such official, the advice of a competent physician should be sought by the teacher or superintendent. Readmission to school also should be by the advice of a physician.

**EXCURSIONS, SCHOOL.** — A term applied to journeys of longer or shorter duration taken by school children under the direction of teachers, primarily for purposes of instruction. Historically the school excursion may be connected with the wandering and begging students of the Middle Ages. The distinct educational value of travel was recognized by most of the writers on education of the sixteenth and seventeenth centuries, including of course Montaigne and Comenius; but here the period of travel succeeded the education of the school, and was not intimately connected with it. More specifically, however, the school journey

received its impetus from the work of Rousseau, under whose influence Basedow incorporated the school excursion as part of the work of the Philanthropinum at Dessau; but this failed, with the rest of his efforts, only to be revived and successfully developed by Salzmann (*q.v.*) at Schnepfenthal. Influenced by Salzmann and Bender, who had made use of school journeys at Weinheim, K. V. Stoy (*q.v.*) introduced the system into the practice school at Jena. The plan received its further development under Professor W. Rein, who combined Ziller's theory on the subject with Stoy's practice, and made the school journey an integral part of the school curriculum. From Jena the plan has been adopted throughout Europe. The short half-day or day excursion is a feature of the German elementary schools. Visits are made to local museums and scenes affording interest from the geographical, historical, and natural points of view, in order to supplement a definite lesson. The longer school journey, as conceived by Professor Rein, serves to focus in a practical way most of the work of the year within certain limits: geography becomes something real when the pupils can see actual concrete instances of what may hitherto have been nothing but names: nature study, geology, botany, become objectified; history receives a concrete background; and the pupils' views and outlook on the world are broadened generally. The world itself becomes a valuable education. School work as developed at present tends too much to be seat and book work. The journey or excursion introduces variety of a valuable character, and teaches the pupil how to educate himself by using his eyes and ears; frequently the backward pupil shows qualities not recognized in the classroom, or the clever pupil finds that he has much to learn in his contact with nature and the world; and both may learn to find pleasure in the open, — a valuable training in these days of crowded town life. Further the contribution to character formation is no slight one: the initiative and freedom which the pupil enjoys is greater than can be possible in the school; the constant contact with other pupils is a valuable social training; while the relations with the teacher can assume another aspect to that in the classroom. Professor Rein's example has been imitated throughout Germany, but more particularly where the Herbartian influences are strongest. In Austria-Hungary, Holland, Denmark, Russia, and England, students of Professor Rein have introduced the school journey as organized at Jena. But other movements of equally educative value have been influenced by these journeys; in Germany numerous societies, some of which are philanthropic, have sprung up to facilitate the traveling of school pupils, but these journeys do not form an organic part of the school work. German pupils can now be found during vacations scattered not

only over the whole length and breadth of their own country, but in the Tyrol, in the Alps, in France and England. With the last country a system of exchange of hospitality has sprung up. In France and Belgium the school journey is frequently given as a reward for good work, although in Brussels a school excursion once a fortnight is compulsory. In England the school journey of the Jena type has had a wide vogue and received an impulse from the successful experiments made in connection with the practice schools of the Manchester University, first under Miss C. T. Dodd, and then under Professor Findlay, who instituted the practice of taking his pupils into the country for a period of two weeks in each year. Pupils from English schools, more particularly secondary, are taken into Germany and France; and no doubt the foundations for peace are being laid in thus giving the younger generation an appreciation of their neighbors, without mentioning the educational benefits accruing. The school excursion in the narrower sense of a short journey with an immediate purpose is receiving favorable encouragement from the Board of Education, which recognizes rambles, excursions, and visits for school attendance purposes (*Elementary School Code*, 1909, Art. 44 b), and teachers are not slow to avail themselves of this power.

The success of school journeys depends largely on careful preparation and organization. The curriculum of the whole year should unconsciously form a preparation for what is to be seen and visited; more immediate preparation may be given a few weeks before the journey. The pupils should receive directions as to behavior *en route*, the amount of baggage to be brought, and a little preparatory exercise. In most cases the pupils pay their own expenses, which in England and Germany amount to \$3 and \$6 each. Poorer pupils should, so far as possible, be assisted quietly from some contributions. A holiday savings bank is a good plan in poor schools. While a definite routine should be observed *en route*, it is not necessary that the time-table should be so rigorously observed as to detract from the truly educational value of the journey. Other important features in organizing a school journey are the securing of lodgings, the provision of guide books, which in some cases the pupils may prepare themselves, and the supply of a small medicine chest. The school journey should be rounded off with a general review; and for classroom purposes its value lies in constant reference to it where objective knowledge is required.

In the United States the school excursion has only recently been employed as a means of instruction, though its use is increasing each year. Visits of teacher and class to the parks and museums of cities are becoming more common, and half-day excursions to the country are now employed in some places.

An all-day excursion on Saturday has become a regular part of the summer vacation school, such excursions often being made to farms and to points of interest some distance in the country. This form of teaching is capable of much greater use than we have so far given it.

**EXCUSES.** — As one means of preventing and correcting unwarranted absences and tardinesses, the schools usually require written excuses from the parent. Such excuses are mere explanations, the demand for which is devised to check truancy or to reveal defects in home control. They are of very irregular effect in different communities, depending on the compulsory attendance statutes, the firmness of school administration, and community opinion.

H. S.

See SCHOOL MANAGEMENT; also RECORDS AND REPORTS.

**EXEMPTIONS.** — In some communities, exemptions from school attendance and school examinations are given to children as a reward for good attendance and high-grade scholarship. The practice is decreasing in the lower schools in particular, owing to the fact that exemption from school duties and opportunities, treated as a privilege or reward, engenders an unwholesome attitude toward two normal functions of school life. When immunity from attendance or examination is regarded as a privilege, it implies an escape from something unpleasant and undesirable.

**EXERCISE.** — See ATHLETICS; CALISTHENICS; GYMNASTICS.

**EXERCISE, OPENING.** — See OPENING EXERCISE.

**EXHAUSTION.** — See FATIGUE.

**EXHIBITION.** — An endowment for the maintenance of poor scholars, either at a school or at a university. It is one of the most ancient, as it is one of the most extensive of modern, methods of promoting education.

The term is derived from Roman law, and means nothing more than maintenance. It occurs in the *Digest* (XXV, iii, 5) in two citations from Ulpian. "Whether any one is bound to maintain (*exhibere*) those children only who are in his power or also those who are emancipated requires consideration." And (*Dig.* XXVII, xi, 3) "The right of alimony (*alimentorum*) for wards is within the Prætor's cognisance. When an estate is large, the measure of alimony is given not by the size of the estate, but by what is sufficient for a moderate maintenance (*quod exhibitioni frugaliter sufficit*)."

Exhibitions for boys at school appear to date at least from the time of the Emperor Alexander Severus. His predecessors had established public schools; he established exhibitions for poor boys with the condition, repeated in the statutes of Eton College one thousand years later, that the recipients should be free born. In England it is recorded by Herman, Archdeacon of Suffolk, writing c. 1070, that King Canute, c. 1020, when he went to any noted minster or walled city, sent there boys to be taught at his expense, not only freedmen and the poor, but also freemen's children.

Perhaps the earliest instance of an exhibition in post-Conquest England is in 1176, when the Sheriff of Northampton accounted for the livery (*de liberacione*) of John, a clerk of Eleanor, Queen of Spain, while he was at school at Northampton at the rate of 2s. a week (*Pipe Rolls*, 22 to 27 Hen. II). Evidence of a similar royal exhibition occurs in a writ of King John to William of Cornhill, 13 April, 1205, "Make the bearer Geoffrey attend school at Winchester and find him reasonable necessities. Let us know what you spend on him, and you shall be given credit for it." But royal exhibitors were not the holders of permanent endowments. The first of these seems to have been connected with St. Cross Hospital by Winchester, founded in 1130, where 100 poor men were daily entertained at dinner, among whom were thirteen of the scholars of the grammar school sent there by the master of the High Grammar School of the city of Winchester. The evidence that this arrangement was part of the original foundation depends on a suit witnessed in 1373. At Durham the Almoner's Register (f. 12) records a deed by which Simon of Farlington (which is in Hampshire, so that he knew St. Cross), Archdeacon of Durham, gave in 1180 the manor of Kyhon Durham, "for the maintenance of three scholars of Durham school, whom the master shall charitably choose, and sent with a tally with images of the Blessed Virgin and St. Cuthbert to the Almoner, who shall provide them with food and drink and lodging in the Almonry."

The two earliest exhibition foundations in France are connected with England. In 1180 an Englishman named Jocius, on his way home from a pilgrimage to Palestine, established at

Paris an exhibition endowment at St. Mary's Hospital at Paris of food and lodging in a separate chamber for eighteen poor "scholar clerks" with twelve *nummi* a month, while seven years later the Count of Dreux established a similar exhibition for poor clerks in the Hospital of St. Thomas the Martyr (Becket) at the Louvre. The term "exhibition" for such maintenance of poor scholars appears to be first used in England in the Merton College Statutes of 1274, which provided for the withdrawal of the maintenance of exhibition (*sustentatio* or *exhibitio*) of a turbulent scholar. Giffard, Archbishop of York, wrote on Mar. 7, 1276, to his bailiff to "maintain (*exhibere*) John Aucher and his two companions attending school at Beverley from Michaelmas at the rate of 2s. a week with their petty necessities" (which the Merton College Grammar School accounts for the following year show to mean shoes, stockings, lights, and the like), "with 36*d.* for their gowns."

The wills of the fifteenth century are full of exhibitions. Thus in 1421 Thomas Greenwood of York and Lincoln gave 20 marks each to William and John Greenwood to learn their grammar. Ralph Snaith in 1472 directed that William Wakefield "be found at scole," and Sir John Pilkington in 1478 gave 6 marks a year to "find John Pilkington to his learning at Oxenforth." In 1501 Robert Constable, sergeant-at-law, gave £20 to his son Marmaduke "for his fynding and exhibition in the University of Cambridge for 3 hole years byginning at 15 years old and £24 for 3 years more exhibition at an Inn of Chancery."

Perhaps the earliest use of the term in precisely the modern sense is to be found in Mulcaster's *Positions* in 1585, when he speaks of people who will "give a scholar some petie poore exhibition to seem to be religious." From this time exhibitions have been the favorite foundation with those desirous of becoming pious founders. While what was chiefly wanted was new schools and the increase of old ones, vanity was more cheaply flattered by the creation of exhibitions which were called after the donor's name. The creation of new secondary schools practically ceased from the Restoration in 1660 to the middle of the nineteenth century. But the flow of exhibition endowments went on intermittently. The Schools Inquiry Commission of 1867 warmly praised exhibitions as the means of bringing the lower-class boy to the top; and the few instances of farmers' or workingmen's sons who became bishops or headmasters or the like by means of exhibitions from the country grammar schools to the universities gave a new impetus to the foundation of exhibitions as building a ladder from the humblest station in life to the university. An enormous further impetus was given to this when, in 1896 and in 1902, large educational funds were put by the State in the hands of local authorities. While

the real need of the country was new schools and the improvement of old ones by the provision of adequate pay for assistant masters, much of the funds was lavished on exhibitions to take boys from the elementary school onwards. About one in ten of the exhibitioners derives any real benefit. Too often the successful exhibitioner, prosperous as a scholar, merely adds to the crowd of underpaid and unsuccessful assistant teachers. Fortunately, the authorities are now directing more attention to the improvement of the schools and the provision for masters. A. F. L.

**EXHIBITIONS, INTERNATIONAL, AND EDUCATION.** — See EXPOSITIONS, INTERNATIONAL, AND EDUCATION.

**EXHIBITIONS, SCHOOL.** — An important, as well as most difficult, problem in schools, both private and public, is to secure the interest of the parents and the support of the community. One solution of the problem is frequently sought in school exhibitions. As not all the exercises of the school admit of a ready performance in public, or afford opportunity of interesting an audience, it is customary to rely upon a display of accomplishments — music, declamations, dramatic performances, calisthenics, or dancing; or upon the products of handwork, such as drawing, woodwork, or sewing. In schools where only literary subjects were taught, exhibitions were formerly limited to declamatory exercises. The evil tendencies of the practice are described as early as 1812 in the *Juvenile Mirror*, published in New York, which points out that as soon as a school exhibition is decided on all regular work is neglected, and everything is turned topsy-turvy "that the children may be taught the art of *spouting*." The pupils are not taught anything useful, but learn by rote pieces beyond their comprehension.

The use of the display of the attainments of pupils in order to enlarge the patronage of private schools was paralleled in the early stage of the public schools, when it was necessary to secure the public support. Public exhibitions, in the elementary schools of Boston and New York, were at times honored by the presence of the President of the United States, the governors of the states, the chief officials of the city, and other distinguished guests. In rural communities, the closing exercises of the schools constituted the chief event of the year, attracting the entire community within a radius of ten or fifteen miles to the open-air presentation of dialogues and plays. Great interest was aroused in new plans for the education of the neglected classes. Hence the schools of Pestalozzi, Fellenberg, Lancaster, Bell, Owen, and Wilderspin were visited "with wondering eyes" by princes and peers, clergy, and all types of educational reformers. Special

occasions for demonstrating the merits of the new schools were found in stated examinations and exhibitions.

With the systematic grading of the schools, examinations ceased to have a public character, and the principal school exhibitions were the graduating exercises. Secondary and elementary schools imitated the college commencement in the conferring of diplomas, the salutatory and the valedictory addresses by graduates, and in many other time-honored features of the college. The ostentatious display of borrowed accomplishments, of dress, of flowers, and gifts, with the consequent burden of expense upon the parents, led to a reaction in favor of simplicity. Rivalry in dress is now discouraged, and a practical address to the graduates has generally replaced the immature productions of the pupils.

The modern curriculum has given occasion for many special forms of school exhibition, which present an exposition of the work throughout a school, or afford opportunity for the comparison of the schools of a city or of different communities. Local exhibitions are commonly made for from one to three days, usually at the close of the school year, and the work of each grade or department is properly arranged, labeled, and exhibited for the inspection of those visiting the school or schools. Sometimes, in larger cities, a collected exhibit is made at some central place at the close of the school year, or on account of some special meeting or occasion during the school year. Such exhibitions frequently last a week or more, and usually attract much local attention. This form of school exhibition is frequently provided in English cities, London having provided many such. For comparative study, specimens of drawing, maps, notebooks, charts, and all the various forms of handwork offer a distinct advantage. The first organized employment of such exhibitions was initiated by the lyceum movement, before the middle of the past century, and furthered by the New York State Education Department. Such were the expectations of the results of a friendly rivalry between schools, that the most sanguine advocates of the exchange of specimens of pupils' work hoped by this means to allay the bitter sectional rivalry then existing, and to avert the war that was imminent.

To the earlier great international expositions (*q.v.*) is to be attributed the first object lessons as to the possibilities of art and manual training; and to the more recent, the objective demonstration of nearly all phases of educational institutions. Pedagogic museums (*q.v.*), as those of Zurich, Brussels, Paris, and Berlin, containing permanent exhibitions of school work, are becoming recognized as necessary in a progressive state and city system. There could be no greater evidence of the growth of an enlightened critical spirit in edu-

educational affairs than a comparison between a school exhibition in New York one hundred years ago and a budget exhibit of the present. Such an exhibit aims, by a complete and graphic presentation of cost, method, and results, to win the taxpayers to the support of the enlarged activities of the schools. The most recent, as well as the most suggestive, development of the idea of school exhibitions, is the Child Welfare Exhibit, in which school work is presented as only a phase in the culture of children. This aims to demonstrate the most approved nursery equipment, diet, toys, and games; the most effective use of parks, libraries, and museums; the best planned Sunday schools, charitable and reform institutions, and the most suggestive school occupations.

Few exhibitions can be entirely free from the criticism quoted at the beginning of this article. Legitimate school work may be sacrificed to purposes of display; false standards may be inculcated through the overestimation of those phases of school work which are readily capable of representation; a fair showing of unaided, unselected work is difficult to secure; the effect upon pupils may be to increase the conceit of the precocious and to discourage those of moderate talent — to arouse an excess of self-consciousness; on the other hand, much benefit may be derived from well regulated rivalry between pupils, classes, or subjects; and through comparison of results improvement may be secured.

To be of the highest value exhibitions should represent the regular work of the school, not that prepared for the purpose; work of entire classes should be shown, rather than the work of the more talented pupils; competition should appear between classes or schools rather than between individuals. While preparation for an exhibition should not be the primary aim of any school exercise, such preparation may be used as an aid to interest and efficiency. All school exhibitions should serve some definite standards of selection. They should be interpreted with respect to the limitations of the purpose and the method of selection, and with the reservation that the most important educational results elude concrete representation. ### EXPERIENCE AND THE EMPIRICAL.

— In Greek theory experience as a source of knowledge and of skill was contrasted with reason. Experience meant the cumulative effect, intellectual and practical, of a repeated series of acts and sufferings of like nature, this cumulative effect covering what was handed down in tradition from previous generations as well as from previous acts of the same individual. Thus it is by "experience" that carpenters are able to build houses: previous acts of building have created in the community a conception of what sort of a thing a house should be; by the same past history various devices have been wrought out; and, finally, by apprenticeship and repeated practice, the individual carpenter has become skilled. In short, experience meant the training and practice which give skill and knowledge how to do in any branch of industry or art. The Greeks recognized an advantage and a disadvantage in this act of learning. The advantage resided in superior ability to deal with particular cases; and practical life, as distinct from science, focuses ultimately wholly in particular cases. The physician cannot cure individual cases of disease simply by his general medical science; the general who is versed merely in the theory of tactics and strategy is not likely to win battles. In all such cases, practice, or experience of a number of like cases leaving a sort of cumulative deposit of instinctive sense and skill, is absolutely indispensable. On the other hand, experience is so linked to habit and routine that, by itself, it is a slow and costly method of acquiring knowledge; and, moreover, is incapable of arriving at true principles or universals. The physician may learn from experience that certain symptoms indicate diseases that are best treated by certain remedial measures; but he must learn from reason how and why such and such remedies effect cures in such and such cases. Rational knowledge, therefore, is alone worthy of the name true knowledge. Science, in short, deals with explanation, with principles, laws, universals. Since habit and practice do not attain to this stage, science requires some-

thing transcending experience, *viz.* reason, *notus*. The geometer is not dependent upon repetition of practical contact with a great diversity of cases; in the degree in which he is truly a mathematician, a knowledge of a triangle may be secured at one stroke of demonstration. Moreover, rational knowledge is final, while empirical at the best is approximate, not necessary, and hence, in every case, true only "upon the whole," or usually. Thus the term "experience" was fixed as an antithetical term to "reason"; it had all the connotations involved in the word "empirical," as when we speak of a physician as a mere empiric.

Roger Bacon was probably the first to break away from this tradition. Medieval science was in such a plight from devotion to traditions which were supposed to embody reason that it was inevitable that some discerning person should perceive that the only hope of progress was in recourse to observation; and Roger Bacon was in advance of his time in his recognition of the possibilities of a control of experience through experiment. Francis Bacon followed Roger Bacon in somewhat vague use of experience as the ultimate source and arbiter of all the sciences. By the time of the later Renaissance the tide was all running in favor of experience; and a curious reversal of perspective took place. To the Renaissance, it was not experience which was associated with the past, with routine, with unanalyzed tradition, but rather authoritative dogmas which claimed to be founded on reason or to be intuitive and axiomatic, and hence not subject to inquiry or criticism. Experience, on the contrary, represented the incursion of the new, the fresh, the conquest of the unknown. With the invention and application of various devices like the lens, experience comes to mean observation of nature operating under the conditions most favorable to discovery.

The development of the mathematical sciences brought about, however, a reaction in favor of conceptual or rationalistic knowledge. On the Continent, the old dualism was reinstated in the form of the distinction between "matters of fact" and "truths of reason." This reaction toward a derogatory conception of experience was strengthened by the fact that Hume had shown that the emphasis put by Locke and his school upon sensation as the central element in observation, or experience, destroyed the validity of all knowledge involving relationship, and hence of all inference. In order to save science, mathematical and physical, Kant was thus led to introduce a new conception of experience; namely, that of a synthesis of a passively given manifold of sense by means of *a priori* active functions of thought. Only on the basis of this *a priori* function could, according to Kant, the universal and necessary character of scientific propositions be justified, and at the same

time their applicability to the changing events of sense perception be explained. The inherent difficulty of the Kantian philosophy — that of showing how two absolutely antithetical elements coming from two opposite sources, one from the thing-in-itself, the other from thought — led his successors to move in the direction of the concept of an "absolute experience," an experience so comprehensive and permanent as to cancel the Kantian dualism.

Meanwhile other developments, partly within philosophy and partly within the biological and social sciences, were making for a radically different conception of experience. The interest from the Renaissance period on in the progress of science had led to the definition of experience in cognitive and intellectual terms. The new view of experience (see PRAGMATISM) reverts, as it were, to the Greek conception of experience as essentially a practical matter, *i.e.* a matter of repeated exercise and of its effects; while it reinterprets practice or action (1) in the light that scientific experimental methods have thrown upon the possibility of a control of experience; and (2) in the light that biology has thrown upon the life process.

The main features of the resulting concept of experience may be associated with the two chief connotations of the popular, nontechnical use of the term; namely, (*a*) to try a thing out, to test in action, and (*b*) to undergo, to endure, to suffer. With the first, or more active sense, experiment and the deliberate control of experience are connected; with the second, or more passive sense, the dependence of the individual upon contact with a world, social and natural, beyond himself. More specifically experience involves, first, an active experimenting with things. Every organism by its nature tries its active powers upon the world around it; it is the very nature of a living being to exercise its organs, and this exercise takes effect in and upon the surrounding medium. In lower organisms, this trying out of the agent in the world of things is blind and instinctive; in higher organisms, in man as he progresses in civilization, it is deliberate and purposive; it involves a forecast of consequences that may follow and the endeavor to manipulate the means requisite to produce these consequences. But in both cases there is some outreaching effort to modify the environment in the interests of life. (See ADAPTATION; CONTROL; ENVIRONMENT AND ORGANISM.) Experience, negatively put, is not mere passive reception; it is not mere acceptance of impressions externally forced upon the living being.

In the second place, this active experimenting with the world results in a changed attitude of the self. The organism has, so to speak, to stand the consequences of its acts. Its actions in modifying things about it modify the conditions which affect its own existence;

these changes may be not only unforeseen, but also out of harmony with the direction of its actions. Nevertheless the agent has to suffer or undergo these results. He "learns by experience" what he can do, as well as what it is undesirable to try to do, since through habit the results become embodied in his own structure.

Experience thus has a conservative, cumulative character, — the phase of habit, of formation of the self and all its powers by what it goes through. And since subsequent experience depends in large measure upon the set and bent given the self, upon its past activities, this involves also a certain preformation, a limiting, of further experience. But experience has also a prospective, out-reaching, projective aspect. The principle of habit does not exhaust experience; it marks only a limit of movement in one direction. Curiosity, variation, invention, discovery, are involved in the active, or "trying on" phase, of experience, just as much as fixation in habitual attitude is in its "undergoing" phase. Which of the two phases, the conservative or progressive, is dominant at a given period of history is a matter not so much of the biological or psychological structure of experience, as of its social standards and aims.

From this point of view, it is possible to effect a reconciliation of the long opposition of the empirical, the *a posteriori*, and the rational and *a priori*. The opposition is not between experience and something transcending experience, but between the functions of habit and purpose in experience, in which the latter suggests new and varying ends, while the former provides the body of means for their effective realization; while consciousness (*q.v.*) marks the focus and stress of the readjustment of old habits to the novel aims. On this account, thought is as truly a factor of experience as is routine; reflection as legitimate and necessary a product as sensation. For thought is the projective tendency of life to vary the environment brought to conscious recognition, so that henceforth it occurs deliberately, not blindly. It is *a priori*, not in the sense of transcending experience, but in the sense of transcending the habits formed in past experience; in being prospective, or reinterpreting the past in the light of a possible future.

This abstract formulation finds a concrete exemplification in educational practice more readily, perhaps, than anywhere else. In various forms, the classic dualism of experience and reason was embodied in educational practice; a fact which was unavoidable, because the philosophic distinction itself grew out of the lack of interaction between custom and reflection, between traditional institutions and scientific discoveries, characteristic of ancient and medieval society. The mechanical arts (see Arts) were to be learned by experience, by practice; the liberal arts appealed to the

higher faculties, and while practice and habituation could not be dispensed with, they were to be used as mere preliminary scaffolding. The bookish (the so-called academic and scholastic) character of education, the absence of concrete materials and appliances, was a natural correlate of the depreciation of experience. With the effort of modern philosophy to rehabilitate the concept of experience came the criticisms of the reformers against this type of education as not genuinely intellectual, but only verbal; and their emphasis upon observation, natural objects, and physical apparatus as indispensable factors of education. The mottoes "from the concrete to the abstract," "induction before deduction," "teach things, not words," "learn to do by doing," are all of them products of the exaltation of the function of experience.

Educational practice inevitably shared, however, in the one-sided notion of experience entertained by empirical philosophy; its neglect of the active and emotional phases of experience in behalf of its purely cognitive aspects, and the reduction of the latter to mere observation with inference excluded. On this account, the efforts of the reformers, as soon as their own personal inspiration was lost, tended to an external and narrow type of education, neglecting the culture of the emotions and imagination and the necessary correlation of inference and reflection with observation, in order that the latter might have educative value.

Since the latter part of the eighteenth century, educational practice, like philosophical theory, has been struggling toward a more catholic and fruitful conception of experience and its uses. It has been endeavoring to overcome the dualism between sense perception that neglects or even excludes thought, and thought that is purely abstract because remote from the concrete materials of observation and action. (See COURSE OF STUDY; EDUCATION.) The hope of educational progress lies in the creation of an environment (*q.v.*) which, while adapted to the pupils' capacities, habits, and purposes, shall provide problems that will evoke and direct thought, or the conceptual function, and that shall organize imagery into a broad and fruitful view of nature and society. Thought, which is generated by the concrete predicaments or difficulties of experience, must be so developed and directed that it will afford a method of clarifying the obscurities of prior experience, of more flexible projection of new ends, and of more efficient control of the means of their realization. The teacher, in short, has to realize that "experience" means primarily action and the accompanying emotional appreciations; and that while these develop in one direction into habits and sense perceptions, they develop, in the other, into conceptions and intellectual systems. The proper

contrast is not between experience and something else higher and better than experience, but between a crude, narrow, and mechanical experience, and an intelligent, enriched, and free, or growing, experience. J. D.

**EXPERIMENT.**—A method of aggressive scientific analysis, to be distinguished from observation (*q.v.*). In observation the scientist waits for nature to produce a phenomenon, and takes as careful note as possible of all the details presented. Thus, the astronomer observes an eclipse of the sun. In experiment the scientist does not wait for nature, but himself produces certain phenomena at such time and place, and under such conditions, as will facilitate the analysis of the process under examination. Thus, if the physicist wishes to study the effect of heat upon metals, he does not wait for nature to change the temperature; he selects a specimen of the metal and varies its temperature at will. The advantage of experiment is that it permits repeated observation under favorable conditions. Furthermore, since the variations introduced are under control, the phenomenon may be studied deliberately from many sides. Thus the effect of temperature on metals may be studied at one time, and the effect of electric currents at another. Natural phenomena are usually very complex, and need to be analyzed. Experimental analysis is a much more aggressive type of analysis than any which can be carried out merely by observing natural facts.

From its very nature, experiment must be recognized as a late form of scientific method. When man first began to study nature, he was content to observe the facts. As soon as he understood some of the laws of nature, he began to modify natural processes for practical purposes. Little by little, he saw that his own modifications of nature furnished favorable opportunities for extending his acquaintance with natural phenomena. Practical experimentation thus preceded scientific experimentation. It was in the physical world that man first performed experiments, for it was

in this sphere that man first controlled conditions enough to make experimentation possible.

Long after the physical sciences had come to recognize the value of experimentation, the biological sciences continued to be purely observational. Indeed, so powerful was the prejudice against any interference with nature in the physiological world that the science of physiology was slow in realizing even the possibilities of observation. In the last two decades, however, more than ever before, there has grown up in physiology a vast body of experimental material. The effects of feeding man and animals in various ways has been very fully studied. The effect of light and moisture on the life of plants has been worked out in great detail.

Psychology and the social sciences were even later in development than were the biological sciences. Like other branches of science, the psychological and social sciences began with mere observation. At first, no one thought of experimenting with mental processes and with social organization. To-day, on the other hand, experiments are freely performed. (See **PSYCHOLOGY**, **EXPERIMENTAL**.) The development of experimental methods in the study of human life led very soon to the demand for a study of educational problems by the same method. This demand has resulted in a body of methods and results known as experimental pedagogy (*q.v.*). There has been much unsystematic experimentation in the schools. Teachers have often attempted to improve their methods of work, and in so far as they changed some well-defined factor of the situation, they performed a strict experiment. Such a change may very properly be compared to the practical experiments of the earliest physicists. Practical experiments prepare the way for systematic scientific investigation. (See **EXPERIMENTAL PEDAGOGY** for further discussion of this matter.)

There are certain phases of natural phenomena which are very difficult to control and which can never be subjected to experimental adjustment. Thus, gravity always enters into every physical experiment; the social environment outside of the school always enters into every experiment in education. The only recourse left to the scientist in these cases is (*a*) to keep the uncontrolled factor, as nearly as possible, constant throughout the whole experiment, or (*b*) to study enough cases so that the results may be checked up in spite of fluctuations in the variable field. Thus, if we wish to study the effect of a certain method of teaching, and are aware that the external social environment will interfere with our experiment, we choose a large number of cases, in some of which the social environment will be favorable, in some of which it will be unfavorable, and by comparing the results of our experiments in all the different cases,

draw conclusions which have a validity that transcends the fluctuation of social environment.

Experimentation thus passes insensibly into statistical inquiry (*q.v.*). In the latter, the phenomenon is recognized as so complicated by uncontrollable factors that safe conclusions can be drawn only after an exhaustive study of many different cases. The emphasis is commonly laid, therefore, in the study of statistics, upon the method of calculating the mass of material. The essential value of statistical study is, however, not in the calculation of the material, but rather in the analysis which can be worked out in spite of the complexity and heterogeneous character of the material. Thus, an investigation may be undertaken of the methods of teaching spelling. Shall lists of words be given which contain many like-sounding words, or shall the words be as diverse as possible? The enormously complex processes which enter into any individual's effort to learn words are likely to discourage the experimenter who is familiar with the relatively much more controllable situations presented in the physical sciences. The student who is equipped with a combination of statistical and experimental methods is not so embarrassed. He faces the complexities of the case, and gives them all many opportunities to operate. He tries one kind of list of words, and then the other. He repeats the effort on dull days and bright, when the social distractions are many and when they are few. He gets enough cases ultimately so that he is justified in feeling assured that only the one factor which he is investigating has been uniformly present or absent. The other factors have fluctuated so irregularly as to neutralize their influence. Such an investigation is truly experimental, although it has been supplemented by the use of statistics.

**EXPERIMENT IN EDUCATION.** — The function of experimentation (*q.v.*) in education falls within two more or less distinct and more or less overlapping rubrics: (1) that conducted

for practical, and (2) that conducted for scientific purposes. Schools are constantly reshaping their usual materials, methods, and devices of administration and discipline, as well as of instruction. Nothing could be farther from the truth than to suppose that schools are static, immobile, hard to influence in the direction of change. On the contrary, school authorities, from their controlling boards through their supervisory force to the individual teacher, are very sensitive and responsive in many particulars to suggestions of change. The course of study; the methods of teaching reading, writing, spelling, arithmetic; the ways of dealing with uninterested and refractory children; the type of school-book and its mode of presentation; and countless other matters of this kind are undergoing constant experimentation. This rubric includes, then, all such changes as are tried not for the sake of experimentation, but for the sake of getting concretely better results in some specific points. None the less, there is hereby supplied an immense body of possible experimental data for controlling the formation and testing of educational theories. What is needed in order to make this specific and casual type of experimentation more available for the science of education is (1) more careful and exact observation of the conditions and effects of such changes; and (2) systematic arrangement for the registration and communication of the results obtained. In other words, a large part of this practical experimentation is now scientifically useless because (1) no pains are taken to record the antecedent state of affairs into which the change is introduced, and to isolate the special consequences which follow from its introduction; and because (2) the results are not recorded and published in such systematic form as to secure cumulative and coöperative results. As a consequence, the same, or very similar, devices and suggested improvements are tried here and there, or, after a lapse of years, even in the same school system over again, without anything being positively learned, or learned in such a way as to secure its own persistence, if desirable, or its own future nonrecurrence, if undesirable. If one compares the pains taken to secure, record, and make publicly available every item of astronomical experience with the scanty and almost accidental methods of keeping track of and utilizing the varied results of educational experimentation, one readily sees the chief source of the backwardness of educational science.

Educational experimentation in the narrower sense refers to changes made not so much for the sake of improving specific and detailed results as for the sake of throwing light on some educational problem. (This type is discussed more fully under EXPERIMENTAL PEDAGOGY.) These two types of experimentation, however, inevitably blend or shade into

each other. If the public realized how much practical experimentation is going on, and how much of it is crude and random, it would doubtless take more kindly than it does at present to experimentation initiated by experts, having for its objective a definitive contribution to some special problem. Scientific experimentation must itself be subdivided into two kinds, according as it is more specific or more general: (1) A body of data regarding the observations, the memories, the habit-forming, etc., of school children is already accumulating, through suitable adaptations of the methods of the psychological laboratory. By experimentation of this sort much light is being shed upon the relative efficiencies of existing methods of teaching reading, writing, spelling, etc., and concerning the value of this and that specific method of forming a particular schoolroom habit. The comparative definiteness and accuracy of such results is often apt to blind those undertaking the experiments to the limitations of their educational value. They are valuable so far as they aid in the evaluation of existing methods used under existing conditions. They are of comparatively little value in criticizing the existing conditions, or in answering the question whether they ought to be continued in existence. There are certain questions of underlying motivation, purpose, and spirit in education which cannot possibly be worked out under laboratory conditions, until they have first been introduced under school conditions; and these problems are educationally the more fundamental ones. In short, laboratory experimentation, or adaptations of the technique of the psychological laboratory, will show what methods in current use are most effective under conventional conditions; they will not test the relative worth of the conventionally current type of education as compared with some suggestive reformed type. (2) For the latter purpose, special experimental schools (*q.v.*) are absolutely indispensable. Their results are less quantitative, seemingly less accurate, and less scientific, just because they are dealing with matters educationally much more important. However, this does not mean that the two types of experimentation are opposed to each other, but that they should supplement each other.

J. D.

**EXPERIMENT STATIONS, AGRICULTURAL.** — See AGRICULTURAL EDUCATION.

**EXPERIMENT, TEACHING BY.** — Teaching through a series of experiments is characteristic of the modern teaching of the natural sciences. Such work is sometimes performed as a demonstration by the teacher, and, more frequently in the higher grades and schools, as an individual experiment by the students. The development of teaching through experiments is part of the general movement for

learning through direct observation. Object lessons, observation work, school excursions, and laboratory experiments or demonstrations are different methods of inductive teaching; the highly controlled nature of experimental demonstrations being the differentiating factor. Sometimes the method of instruction by experiment is called the method of "discovery," or "rediscovery." Such a use of terms is loose, inasmuch as there is little or no inventiveness on the part of the student in the devising of apparatus or the arranging of conditions. These are all prearranged by the instructor so as to make a conclusion fairly obvious. Teaching through experimentation is a highly rational representation of scientific facts rather than a rediscovery. It should be used with a definite knowledge of its limitations.

H. S.

See articles on the various Sciences; **INDUCTIVE METHOD**; **LABORATORY METHOD**; **DEMONSTRATION**; **OBJECTIVE METHOD**.

**EXPERIMENTAL PEDAGOGY** or **EXPERIMENTAL EDUCATION** (also **scientific** or **empirical pedagogy**).—The terms coming into general use to designate the second type of experiment in education described above under that title. Current discussion has not settled whether the term shall be limited in its application to the first of the two kinds of scientific experimentation described above; namely, that conducted under laboratory conditions; or whether it shall also include the more general observational work, such as was conducted by Herbart and his followers throughout the last century. The more recently developed school of investigators, using methods borrowed for the most part from experimental psychology, are claiming the exclusive right to the term. The present article presents this phase of the subject. The more general aspect will be presented under the titles **RESEARCH IN EDUCATION**, and **EXPERIMENTAL SCHOOLS**.

Experimental pedagogy has received its name because of its emphasis on experimental methods, though it embraces all pedagogical facts obtained by scientific investigation, regardless of the methods used. The movement to establish a pedagogy of this sort is comparatively recent and has plainly grown out of the scarcely older science of experimental psychology, whose methods it largely follows and whose results it extensively utilizes. Experimental pedagogy, therefore, implies an opposition to a pedagogy of a more theoretical character based upon some philosophical system or preconception of the aim of education, and upon the casual observations of educators. Those who support the movement for experimental pedagogy hold that the results of such methods of investigation must necessarily be partial and individualistic and lacking in certainty and concreteness.

Although experimental pedagogy follows the lead of psychology in both its methods and its results, it relies also upon results of all the sciences whose facts have significance for education, such as anatomy, physiology, anthropometry, pathology, logic, ethics, and aesthetics. It borrows facts from all these fields, but regards them from an entirely different point of view; namely, that of education. It is therefore an independent science. While experimental pedagogy is dependent for its facts to some extent upon all of the sciences mentioned, it is chiefly indebted to investigations of the physical and mental life of the child, such as are afforded by child psychology and physiology, and the pathology and psychopathology of the child. The child thus becomes the object of exact investigation, and pedagogical principles and methods are decided upon the basis of scientific observation of their effect upon his training and development.

Experimental methods always have certain advantages over haphazard observation. They introduce precision and definiteness, because the conditions under which the phenomena occur are controlled by the investigator. The investigator is, therefore, able to vary the conditions in such a way as to make an analysis of the truly causal elements. For the same reason the results of any investigator are open to confirmation by other investigators who can repeat the original conditions. One other advantage to be gained from experiment is that the phenomena to be observed may be made to appear by the investigator without the necessity of waiting for them. Besides experimental methods proper, experimental pedagogy makes extensive use of statistical methods of investigation, which also tend to free its results from the errors of faulty deductions based upon the purely qualitative observation of individual educators. The application of experimental methods to the investigation of pedagogical problems involves the same kind of procedure as in experimental psychology, and also involves the same difficulties. It has, however, the added difficulty that the subjects of the experiment are always children, who are less likely to be able to report their own experiences correctly, and whose experiences are more likely to be misinterpreted. This difficulty, however, is by no means insuperable, as may be seen from the large mass of information which this new science has supplied. Among the most important of the experimental results are those which have been obtained from investigations of the nature of the child's mental and physical development and its stages, investigations of the individual differences and mental capacities of children, investigations of fatigue and economic methods of learning, besides special investigations into the methods and results of teaching drawing, writing, arithmetic, reading, etc. E. **EXPERIMENTAL PSYCHOLOGY.**— See PSYCHOLOGY, EXPERIMENTAL.

**EXPERIMENTAL SCHOOLS** (also *New Schools, Demonstration Schools*).— The discovery of large and novel principles in teaching, such as seek their fulfillment in a complete process of child development, issue almost of necessity in the endeavor to found a school in which they may be realized, or at least tested by experiment. True, some of the earlier reformers, such as Locke and Herbart, watched the relation of theory to practice as private tutors to one or two children; but with Pestalozzi the idea became firmly established that reform must be both studied and demonstrated in an institution designed for the purpose. Hence many forms of restless inquiry after truth in matters of schooling have taken shape in New Schools or Experimental Schools, from inferior enterprises conducted by charlatans to those which have exercised a profound influence on progress. The efforts of Froebel can be regarded as typical; typical too in this sense that the work of the reformer, especially if it be copied in detail by disciples, tends to crystallize into a system and eventually to resist further change; particularly when, as in the case of the kindergarten, it secures recognition by the state authorities and is modified to suit the necessities of a public system. The Herbartian pedagogy is another striking example of the tendency: the very completeness of this *System der Pädagogik* has hampered its advocates in the face of new aspects of truth which have appeared since Stoy and Ziller formulated their doctrines. At the present day a perplexing variety of institutions can be discovered at work. In America the most important have been definitely associated with institutions for training teachers; and this is a wise arrangement, for the reformer cannot spread his new gospel unless he find adherents. In a list of such schools recently published are found not only the Horace Mann and the Speyer School, and the schools connected with the University of Chicago (which are reaping the harvest sown by Francis Parker and John Dewey), but schools at Hyannis, Kalamazoo, and Columbia, Mo. The list might be widely extended, for every training school is *ipso facto* "new" or

"experimental" in so far as those who train teachers are expounding the newer truths of child nature and are exhibiting these in the expanding life of school children. It is on this ground that the present writer chose the title *Demonstration School* as exhibiting more clearly the common purpose that the reformer and the professor of education must have in view. The Fielden Demonstration School in Manchester, England, was expressly founded to supply the needs of a university department of education, and the extent to which its teaching is "new" or experimental will depend upon the quality of the theoretical pedagogy taught in the university from time to time. The title has now been adopted by the English Board of Education, and there are now a number of public elementary schools to which this name has been attached in order to signify that the school has some sort of connection with a training college. But there is no guarantee that the schools to which this title is allotted are actually demonstrating the ideas of lecturers who expound curriculum and method; they are in fact nothing more than practice schools under a new name, *i.e.* schools under the ordinary régime in which students are specially invited for observation and practice. Nevertheless a step has been gained in recognizing the need for associating theory with practice, and these selected schools will no doubt tend as time goes on to be set more and more apart for the distinctive task which the title implies.

In Europe the great majority of schools which aim specifically at reform had no connection with training; besides the one at Manchester, the only school generally known is the famous *Übungsschule*, directed by Rein since 1885, at Jena. The group of schools which are now exercising the greatest influence trace their origin to the New School at Abbotsholme, England (*q.v.*), founded by Dr. Cecil Reddie and others in 1889, a boarding school receiving boys at high fees, and educating them largely in the open air, with a vigorous corporate life. Bedales School (*q.v.*) in Surrey is of the same character, and receives both boys and girls. Dr. Lietz, formerly a student under Rein at Jena, was one of Reddie's chief disciples, and has founded three schools, called *Landerziehungsheime*. There are at least a dozen other boarding schools bearing this title in Germany, Austria, and Switzerland, which follow more or less nearly the ideas of Reddie and Lietz. Their success may be regarded as a reaction against the ultrabureaucratic and conservative tendencies in the state secondary systems, and they as the successors of reformed schools in the earlier half of the century. Institutions of a similar type both in France and in America are well known. They tend of course to become exclusive in status, because of their dependence on wealthy patrons.

In contrast to these, a number of New

Schools are to be found which do not aim to receive children as boarders, and are concerned with primary rather than secondary education. Froebel's experiences may be treated as typical of a situation which recurs again and again. In his earlier years he established a boarding school at Keilhau, designed on lines which recall those of the *Landerziehungsheime*, but his way was blocked by state control, and Keilhau still flourishes as a boarding school, but makes no pretensions to reform. Froebel then turned his regard to the younger children, and it is with these that most of the present-day reformers are concerned. For both the psychologist and the teacher have a clearer ground for experiment and progress when they receive their scholars in earlier years, at a stage, too, when the state system is not so concerned to control the results by examination tests; and in an environment where the parents and the community can be associated in a social effort for the rising generation. The Ethical Culture School, New York, the King Alfred School, London, the Settlement School, Moscow, some half dozen schools in Holland, Dr. Gardelli's *Ecole Nouvelle* in Milan, Dr. Kersesten's *Versuchs-Schule* at Munich may be cited as examples of enterprises which are always being set on foot. Such schools are usually hopeful of being able to carry forward their scholars through the secondary stage also, but they find parents unwilling to forfeit the material benefits gained by sending their children to the approved public institutions for the completion of secondary schooling.

A few words may suffice to indicate the trend of the reforms which such schools seek to achieve. To the superficial parent new subjects of study are the chief attraction: arts and craft, nature study, manual exercises, hygiene, have a prominent place; the formal drill of the large school is replaced by spontaneous activity. But the reformers themselves usually take wider views, some of which are the outcome of scientific research in biology and psychology, or, still more recently, in sociology; definite questions are proposed, and the school makes an experimental endeavor to answer them. Of this type Dewey's work in Chicago is an illustrious example. But most of these endeavors spring from impulses not so clearly formulated, but more readily welcomed by parents who share them — impulses for the regeneration of society in the large sense. These reformers are social reformers to begin with, and are teachers because they are thrown back on the school as the readiest means for the achievement of their ideals. Dr. Reddie's school began, for example, in association with Edward Carpenter and other ultra-socialists, although it soon severed itself from that alliance. Hence not only do we find all the novel subjects, such as manual training, playing a part, but the corporate life of the school, its relation to parents, the relation of the

sexes, the attitude of the teacher and child toward religion, — these are all matters in which the reformers break away from tradition.

**EXPERIMENTAL SCIENCE IN EDUCATION.**—See EXPERIMENTATION; SCIENTIFIC METHOD; and the special subjects BOTANY, CHEMISTRY, etc.

**EXPERIMENTATION, LOGIC OF.**—In the control of discovery and proof, that is to say, of the logical processes concerned in the formation of ideas and beliefs, experiment performs a double rôle. On the one hand, it is employed to vary the facts that are open to observation, and thereby to facilitate the formation of new views, new theories and hypotheses simply as suggestions, ideas which may or may not be valuable and valid. Habit and custom tend rapidly to fixate beliefs and thereby to bring about an arrest of intellectual life. So far as things present themselves in regular and uniform ways to which we have become "used" or accustomed, we make habitual reactions, and thought, or reflective attention, is not required.

Experiment operates to change the customary state of things, and thereby to present challenges to thought, seeming discrepancies, unexpected phenomena, that require explanation (*q.v.*). Experiment does this in three ways. (1) It intensifies conditions which are usually too minute to be noticed, and which therefore are not taken into account in inference. (2) It isolates conditions which are usually so absorbed or covered up by other relations as to escape attention. It rearranges them so as to form a different perspective, thus giving a shock to vision. (3) It combines things that rarely come into conjunction with one another, or that combine under conditions of violence unfavorable to observation, in steady and recurrent ways, so that the observer can see what is going on. Taken in this sense, experimentation includes the use of all devices (microscopes, telescopes, staining fluids, registering apparatus, etc.) which are intentionally employed to increase the range, the detail, and the accuracy of ordinary observations, thereby

extending and safeguarding the use of observation as stimulus and food to thought.

After an idea or hypothesis has been formed and elaborated on the basis of the new data provided by experimental observation, the idea must be tested or verified. This means that the idea must be employed as a plan and method of conducting new observations under test conditions. That is to say, the conditions or causes called for by the hypothesis must be brought into existence with a view to seeing if the effects or consequences, theoretically deduced, follow in accord with the requirement of the hypothesis. To substantiate the theory by reference to the conditions which originally suggested it would be to reason in a circle; to substantiate it through new and independent observations is good as far as it goes, but defective except as these new observations have been framed so as to correspond to the terms of the theoretical explanation and thereby adapted to the purpose of testing.

So far as the stimulation and guidance of reflective thought are concerned, school conditions leave much to be desired. They are much better adapted to the acquisition of a body of fixed information than to investigating operations of inference, discovery, and proving. The absence of opportunity both for initial experimentation to supply stimulating challenges to thought, and for concluding experimentation to test the worth of the ideas reflects the intellectual conditions which anteceded the gigantic forward movement in science following the general adoption of the experimental method. Even when laboratories, etc., are introduced, they are often used simply as devices for acquiring an additional store of information or for learning a special technique of manipulation, rather than as an organic factor of the process of awakening and fruitfully directing thought. On the other hand, technical equipment and apparatus are not required to any great extent in employing the logical method of experimentation in many school subjects. By questioning, by simple constructive devices, children may be led to take account of data which they have got used to ignoring, to entertain, consequently, new problems (*q.v.*), and to frame hypothetical modes of solution and explanation. They can then be held responsible for the definiteness and fullness of the idea, and also for suggesting ways in which the idea may be tested, and for going as far as conditions actually permit. Such methods of instruction, intelligently employed, will go farther in forming a genuinely scientific attitude of mind than will an elaborate equipment of technical apparatus employed without regard to its rôle in the provocation and guidance of reflection. Moreover, it will create a natural demand for such additional equipment as may be genuinely needed, and will ensure its proper educational use when secured.

**EXPERT, EDUCATIONAL.** — A person who by virtue of his special scientific and professional training and his practical experience is so thoroughly informed and skilled in matters of educational method that he is competent to testify on matters of opinion presumably not within the knowledge of men in general, or even within the information of teachers in general. The actual special use of such persons apart from the regular supervisory staff of officials is recent. It is an increasing practice of late for private schools, and even public school systems, to employ a school official from outside to examine the school organization and instruction. The usual method is to observe and examine the school for a week or more, making comparative and standard tests of efficiency, the whole inquiry ending in constructive suggestions. The use of a group of experts on special boards of inquiry into the competency of school systems is just beginning in our larger cities. Occasionally a school system has maintained an advisory educational expert (usually one of the educational faculty of a neighboring university or normal school) upon part time, for the purpose of counseling the board of education and the supervisory staff during a transitional period, as in the formulation of new courses of study, or the introduction of vocational schools, etc. H. S.

See **TEACHING, PROFESSION OF**; **CENTRALIZATION**; **CITY SCHOOL ADMINISTRATION**.

**EXPLANATION.** — The function of explanation presumes the existence of some fact or event which is apparently an exception or anomaly. Only that needs explanation which awakens curiosity or surprise. "Explanations" that do not start from what is felt to be a difficulty (or to offer opposition to the usual way of looking at things) are only verbal. Perhaps no mistake is more frequent in teaching than to proffer explanations of matters before pupils have been brought to recognize any problem that needs attention; or than to require from pupils explanations of what to them is obvious, because of familiarity, or else inexplicable, because wholly strange.

Psychologically, explanation always consists in assimilating the strange to the customary, the unexpected to the habitual, the novel to the familiar. One always feels at home in what is familiar; no matter how many difficulties may attend the subject matter in the abstract, mere familiarity glosses over or covers up all such difficulties in the concrete. The familiar

feels plain, clear, easy, natural, matter of course. Hence to reduce any exceptional or disturbing fact to the rank of the familiar is to make it plain — to explain it, or clear up its mystery.

The practical educational problem relating to explanation has, therefore, to do with the proper adjustment to each other of the familiar and the novel. It consists, on the one hand, in presenting the usual, the eustomary, in such a way that pupils realize that there are strange things, things needing investigation and explanation, in what had seemed to be a matter of course. Genius itself has been defined as the power to detect cause for wonder in the ordinary. On the other hand, the educational problem has to modulate, as it were, from the extraordinary and mysterious thing over to what is already so mastered as to be familiar. In effect, explanation operates by inserting a number of intervening steps or terms, which, taken one by one, span the gulf between the familiar and the strange.

Logically, theories about explanation have been of two kinds. According to one view, explanation is bringing a particular under a general or universal, or a fact under a rule or law, the law under a general law, etc., — what is technically known as "subsumption." The objection to this view is that it is committed to certain "ultimate principles," which, being the source of all explanation, are themselves wholly inexplicable, or mysterious, so that they have to be accepted dogmatically or taken on faith. It also overlooks the fact that a great deal of explanation does not consist in bringing a particular fact under a general principle of law, but in assimilating a strange or peculiar fact to a fact with which we are already acquainted, by means of some general principle. These objections, worked out, lead to the view that the logical essence of explanation is placing in a system, that is, in a group of interconnected facts. Facts and principles reciprocally explain, or clear one another up, on this view, because they are both involved in systematized knowledge. J. D.

**EXPOSITION, RHETORICAL.** — See **COMPOSITION**.

**EXPOSITIONS, INTERNATIONAL, AND EDUCATION.** — The popular mind usually thinks of expositions as a development of the latter half of the nineteenth century. This is correct only in the officially international character which expositions then assumed, beginning with the London Exposition held at Crystal Palace in 1851. As a matter of fact, expositions antedate the Christian era, and were usually connected with certain recurring religious festivals. Roman festivals of this nature were always accompanied with the exhibition and sale of merchandise, and the performance of plays and games. In fact, the three main divisions of an exposition to-day

-- the exhibits, the amusements, and the educational congresses -- have their respective counterparts in all of the ancient fairs of Europe and Asia. The market fairs of the Middle Ages were a continuation of the same idea, and were usually held under the warrant of the lords spiritual or lords temporal, to whom a large royalty was paid for their protection and support. Some of these fairs became famous for their extent and patronage, such as Beaucaire and St. Denis in France, Leipzig in Germany, Southwark in England, Hurdwar in India, and Nijni-Novgorod in Russia.

The development of the modern exposition has generally been attributed to the genius of Napoleon, who encouraged their frequent holding in Paris for the sale of French industrial and art manufactures. No nation has held so many fairs of national and international scope as France. The first international exhibition proper was held in London in 1851, and is so denominated because of the official invitation from the government to all civilized countries to participate, and because of the exhibits covering every phase of human endeavor. Eight others have been held since that time, -- four in Paris, in 1867, 1878, 1889, and 1900; one in Vienna in 1873; and three in the United States: Philadelphia, 1876; Chicago, 1893; and St. Louis, 1904. Two others are in contemplation, one at San Francisco in 1915 to celebrate the completion of the Panama Canal, and the other in Japan in 1917.

Every exposition, perforce, has been educational, as the interchange of ideas and methods has been no less general and influential than the interchange of commodities. This idea reached its culmination at St. Louis in 1904, where the appeal to Congress for funds, to the states for support, and to foreign nations for coöperation was made upon this basis. Education in its broadest sense was meant, -- the education which comes to people in observing art and architecture in heroic models; in studying exhibits grouped in relation to their interdependence upon each other; and in watching processes in connection with these exhibits which take the raw product and under the eyes of the beholder transform it into the finished product. At such an exposition, it can easily be inferred that the science of education, its methods and results, would receive the most careful attention.

It is not within the scope of this paper to trace at length the effect which the successive exhibits have had upon the development of education methods in various countries. Here it is only proposed to give the facts concerning the participation of education in expositions and point out its remarkable growth in exposition activities. There is no record of educational exhibits playing any part in expositions prior to the Paris exposition of 1867. A few miscellaneous art pieces prepared by schools were shown from time to time, but more for

their novelty and excellence of workmanship than as illustrative of any mental training. At the first international exposition in London in 1851, education was not recognized in the official classification, and had no department assigned to it. There were some exhibits installed under the head of "Civil Engineering," and others under the head of "Art," which could be termed educational, but they were accidental rather than premeditated.

It is interesting to trace the introduction and development of education in exposition classifications, as it is coincident with the recognition of education as a fundamental science and the basis of all other arts and sciences. The completely organized exposition of Paris in 1867 was the first to give education a definite assignment in the exposition. It was spoken of in the official report as "A judicious innovation introduced by the Imperial Commission." Group 10, under which the educational exhibits were installed, had the very peculiar designation of "articles exhibited with the special object of improving the physical and moral condition of the people." Many of the exhibits made under this heading would be classed under social economy at the present time, or under sanitary engineering. The exhibits made by the schools at this exposition were desultory and scattered, and show no signs of a logical or orderly arrangement. It is curious to note that the sole entry from the United States under this heading was "specimen of a Western primary school and school furniture," made by the state of Illinois. The Italian and French art schools made the only notable exhibit in the educational field at this exhibition.

At the Vienna exposition of 1873, the official classification, under Group 26, provided for "Education, Teaching, and Instruction." The first logical subdivision under this general head was also made at this exposition, and four classes were provided, for elementary instruction, middle instruction, professional and technical colleges, and universities. It is pleasing to note that the United States commissioner to the Vienna exposition made some effort to secure a very complete set of education reports, and some maps and statistics. Through his efforts thirty-three states and thirty-seven cities and towns contributed various material. The city of Boston made the largest and most complete exhibit in the United States section, and won many awards for its drawing and written work. There was a more general participation by nations in the educational department at this exposition than had occurred before. While the exhibits were grouped under the four general heads given above, they were incomplete and scattered in character.

The Centennial Exposition at Philadelphia in 1876 missed the opportunity of improving upon the Vienna classification, and a retrograde

## EXPOSITIONS

movement is noticeable. Education was recognized as Department Three, under the title of "Education and Science," and seems to have been a rather hopeless mixture of education and the liberal arts. In spite of this, however, the exhibits were more logical and of more general interest than in any exposition theretofore. They were installed in the gallery of the main building of the exposition, were extensive in character, and while there was no care taken for logical arrangement, there were many instructive lessons to be drawn from the material shown. The wonderful exhibit of drawing of the Boston schools, and its effect upon the schools of the country, is historic, and will be treated under another head. The foreign exhibits at this exposition were also noticeable, particularly the Swedish sloyd and the French and Italian art schools.

Education had now become a recognized factor in all international expositions, and in the Paris expositions of 1878 and 1889, Group One was assigned to art, and Group Two to education. At both of these expositions the application and processes of the liberal arts were included in the group, but a separate class was made for each of the three main divisions of education, namely, primary instruction, secondary instruction, and superior instruction. It lies hardly within the scope of this article to discuss the nature of the exhibits at these two expositions. Space in the galleries of the buildings surrounding the Champ de Mars was assigned for the installation of the material, and there was a very extensive participation on the part of both France and the foreign nations. As might be supposed, the exhibition of 1889 was the more complete and interesting, although the classification was exactly the same at both expositions. Historically, the exposition of 1878 was of greater interest, inasmuch as the dissatisfaction with the exhibit of the French schools, in addition to appeals from chambers of commerce and large manufactures on the decline of technical skill, brought about a serious consideration of the subject by the French government, and led to twenty years of agitation and statutory enactments, which culminated in the establishment of the well known schools of commerce and industry under the supervision of the French Ministry of Commerce. The participation of the United States in both of these exhibits was extensive so far as quantity of material was concerned, but no attempt was made to show thoroughly our system of education. An exhibit of freehand drawing from the schools of Boston was again the chief feature of the United States exhibit at these expositions. In fact, nine tenths of the entire educational exhibits at expositions were up to this time drawing and art work. The statistical chart first began to play an important part in 1889.

At the World's Columbian Exposition at Chicago in 1893, education was relegated to a

## EXPOSITIONS

minor position and made a group under Liberal Arts, medical apparatus preceding it, and printing and publishing following it. Judged as a classification, it was inferior to either of the preceding Paris expositions. In spite of this lack of official recognition, the installation was superior to that of any exhibit before made, and although the space assigned was in the gallery of the liberal arts building, it was ample. For the first time an attempt was made by the various states to show by a graded and continuous series of work the complete public school system. The foreign participation was not as general in this exposition as it should have been, but the German educational exhibit was particularly notable for its excellence, especially in higher education; the French exhibit was also thorough and interesting.

It remained for the French at the Paris exposition of 1900 to make the first proper official recognition of education in the classification, and to give a scientific development to the subject. For the first time, education was made Group One in the exhibit classification, for the reason, as stated by M. Alfred Picard, the Director-General, that education was recognized as the source of all progress and the basis of all human endeavor. Liberal arts was divorced from education for the first time, and six classes were established under the educational group: (1) primary education; (2) secondary education; (3) higher education; (4) art education; (5) agricultural education; (6) special industrial and commercial education. Unfortunately, the space assigned to the educational group in the galleries of the buildings on the west side of the Champs de Mars was inadequate, and many exhibits were installed in other parts of the grounds. The participation on the part of other nations was very complete, and the United States, Japan, Russia, England, and Hungary made particularly extensive and thorough exhibits. The German exhibit at this exposition was almost entirely confined to apparatus connected with the university and technical education. It is interesting to note that England for the first time made an exhibit in the educational section of an international exposition. The United States exhibit at the Paris exposition was distinctively national in its character. The best work and the most improved methods in each of the classes under the education group were displayed irrespective of source. The exhibit of the colleges and the universities was based on the same principle. The exhibit was arranged according to the departments of university instruction, and any college or university might contribute material to any one or more of the departments. The exhibit was very complete in illustrating by maps, charts, photographs, and written material the work of every grade and department, from the kindergarten to the University;

and while lack of space was perhaps the compelling motive for this arrangement, it turned out to be by far the best arrangement from the national standpoint. It prevented the duplication which would necessarily arise by recognizing state and city exhibits, and gave a concise logical view of the entire educational system. It demonstrated also the fact that, although there were at that time forty-five states, each with a supposedly separate educational system of its own, they were all, in fact, the same, with no more variation than local color or prejudice might afford. This is attributable to the influence of the United States Bureau of Education, which, under the lead of its Commissioner, Dr. William T. Harris, had for years served as a judicious and respected adviser to school superintendents throughout the country; and to the influence of the National Education Association (*q.v.*), which, through its annual meetings, had served as a clearing house for educational ideas, and brought into close and harmonious relations the educational leaders from every part of the country.

This exposition also brought out the radical difference between the schools of the United States and those of France and other nations under its sphere of influence. It emphasized the vital problems of educational life by placing side by side in contrast the many systems evolved from the various relations of the governing and the governed. The question most general in its application and most diversely represented at the exposition was to what extent the social and industrial development of a nation warrants specialized training at public expense in elementary schools.

It is interesting to note that funds were raised by the city of Manchester, England, with which the entire United States exhibit was transported to Manchester at the close of the exposition, and there remained open to the public from January to March, 1901.

At the St. Louis exposition of 1904, education received its highest recognition in exposition practice. The entire St. Louis classification was constructed by men who had been trained in the Chicago and Paris expositions, and was revised by experts in every branch of art and industry, and has since stood as a model for every exposition held. Education was made Group One of the classification on the principle enunciated for the Paris exposition of 1900, and was peculiarly appropriate, inasmuch as the idea underlying the entire St. Louis exposition was educational. In addition to the Paris exposition classification, two groups were added, namely: "Education of defectives," which had theretofore been included under charities, and "special forms of education," including summer schools, extension courses, etc. The classification read: "Department 'A'—Group One, elementary education; Group Two, secondary education;

Group Three, higher education; Group Four, special education in fine arts; Group Five, special education in agriculture; Group Six, special education in commerce and industry; Group Seven, education of defectives; Group Eight, special forms of education."

The crowning recognition given to education at this exposition was the assignment of a separate building covering five acres of ground in the very heart of the exposition for the use of the department. This marked an era in the development of education at expositions, and permitted a strictly classified arrangement of all material exhibited in accordance with the theory of the classification above mentioned. The participation was very thorough, nearly all of the states of the Union participating, and all of the leading colleges, universities, and technical schools. Following out the idea which underlay the exposition as a whole, an exhibit of processes was installed with success for the first time at an international exposition. The schools of St. Louis maintained daily classes in kindergarten, domestic science, and industrial training. Classes for the deaf and dumb were in actual operation throughout the exposition season, and a business school course was also successfully maintained. The agricultural and mechanical colleges of the United States, in their remarkable collective exhibit, carried on regular laboratory experiments throughout the season. Other illustrative work in music, art, and other subjects was given from time to time in special lecture halls or recitation rooms. Other activities of the school or college classroom were produced during the exposition period.

The foreign nations which made the most extensive exhibit at St. Louis were England, France, Germany, Italy, Sweden, Belgium, Japan, China, Mexico, Cuba, Brazil, Argentina. No extended mention can be made in this space of these exhibits, but they were all in accord with the theory of the exhibit. Perhaps the most noticeable was the wonderful technical exhibit of the German universities. The first exhibition of Chinese educational work ever made at an exposition was interesting in its comparison of the old education with the modern introduced by foreign auspices in seaport cities. Three things, for which the St. Louis exhibit stands preëminent, are its scientific classification, the provision of a separate building for education, and the success of the "working exhibits."

No mention is made in this sketch of the many education exhibits made at national expositions, such as Nashville, Omaha, Charleston, Buffalo, Portland, and Seattle in this country, and Brussels, Antwerp, London, and other places abroad, inasmuch as they were simply replicas on a much reduced scale of exhibits made in international expositions.

**EXPRESSION.** — See EMOTIONAL EXPRESSION.

**EXPRESSIVE SUBJECTS.** — Those subjects which call for a large amount of self-expression or action (*e.g.* manual training, music, drawing, etc.). They are distinguished from the formal (*e.g.* reading, writing, arithmetic, etc.) and content subjects (*e.g.* history, geography, literature, etc.). The expressive subjects represent the latest acquisitions to the course of study. In the broadest sense the expressive activities of the school include not only the active subjects mentioned, but also the play and social activities of school life and the expressive aspects of the older subjects, more particularly the oral and written composition of the language period. H. S.

See COURSE OF STUDY, THEORY OF; CONTENT SUBJECTS; FORMAL SUBJECTS.

**EXPULSIONS.** — The expelling of pupils from school is scarcely used in modern disciplinary practice in the lower schools. The change of public attitude toward the function of elementary education in particular accounts for the discontinuance of expulsions. Education is regarded as a duty, not a privilege. The school laws compel attendance between certain ages, and the deliberate expulsion of a child by the school authority is incongruous with the idea of compulsory school attendance. If a child is not amenable to school discipline, he is merely suspended for the period necessary to discipline him, or is sent to a parental school or some other special institution specially devised to deal with juvenile incorrigibles. The practice of expulsion has a larger usage and warrant among higher schools and private schools. H. S.

See SCHOOL MANAGEMENT; TRUANT SCHOOLS.

**EXTENSION.** — See SPACE.

**EXTENSION WORK.** — See ADULTS, EDUCATION OF; CORRESPONDENCE SCHOOLS; EVENING SCHOOLS; LECTURE SYSTEMS, PUBLIC; UNIVERSITY EXTENSION.

**EXTENSIVE METHOD.** — Any method of treating a subject which aims at a broad survey of the field rather than a highly detailed command of selected or typical aspects. In this sense a comprehensive treatment is contrasted with an intensive method of study. The relative value of extensive and intensive methods is a matter of discussion in almost all the so-called content subjects such as natural science, history, geography, literature, etc.

H. S.

See METHOD TEACHING; INTENSIVE METHOD; EPOCHAL METHOD.

**EXTERNAL OBJECT.** — The phrase "external object" or "world" is indicative of the peculiar problems of epistemology (*q.v.*). Mind, or consciousness, having been conceived as a peculiar private possession of an exclusively individual soul or self, the object of knowledge must be conceived as "external." A great variety of different relations have been, as a matter of fact, lumped together and confused under this caption. There is (1) the problem of space, whose elements are all external to one another; (2) of the relation of the body, as the organ of the self, to the rest of nature, which is external to the body; and (3) of the purposes of an agent to the natural conditions which are indifferent to these purposes or which resist their realization. If the problems appertaining to these relations be distinguished and disentangled, it is doubtful whether any special problem relating to an "external" object or "world" will be left. J. D.

**EYE.** — **Structure.** — The eyeball is set in a cushioned socket, against which it is held, and rotated, by means of three pairs of antagonistic muscles. It is approximately spherical in form, and has a maximum diameter of about twenty-three millimeters. The interior is divided into two chambers: the anterior chamber extends from the cornea to the iris and lens, and contains the aqueous humor; while the posterior chamber extends from the lens to the retina, and contains the vitreous humor. The outer wall of the eyeball is composed of three layers: (1) The sclerotic is a tough integument which covers the posterior sphere; its anterior process constitutes the (ellipsoidal) cornea; (2) the choroid consists essentially of a deposit of dark pigment; its anterior process constitutes the iris, in the center of which is a variable aperture, the pupil; (3) the innermost coating is the retina, which consists of an intricate network of receptors, connectors, fibers from the optic nerve, blood vessels, pigment, etc. The retinal structure is exceedingly complex, but the mechanism may be represented schematically as a system of bipolar and ganglion cells which bring the sensory end organs (the rods and the cones of the posterior layer) into communication with the fibers of the optic nerve (anterior layer).

The rods and the cones are not distributed uniformly over the whole retinal surface. At the region where the optic nerve enters the eyeball, there is a blind spot where sensory organs are wholly lacking; and in the fovea centralis (the region of clearest vision) only cones are found. In the paracentral region the cones predominate; while, as we proceed toward the periphery, the rods become relatively more and more numerous. This fact, together with other evidence, has led to the supposition that the rods are the more primitive, and the cones the more highly developed end-organs of vision. Little is known regarding the details of the retinal process which gives rise to visual sensation. Numerous attempts have been made to account for the phenomena of retinal stimulation, — the theory of Hering being most generally accepted, although the theories of Mrs. Ladd-Franklin and von Kries have also won adherents.

The movements of the eyeball are accomplished by means of six muscles, four of which (*recti*) apparently have to do with movements to the right, to the left, upward and downward, respectively; while the two oblique muscles, which have a lateral attachment and operate through pulleys, serve to reduce or prevent the torsion of the eyeball.

Accommodation, or change in the refractive power of the ocular system, is brought about by means of a variation in the form of the crystalline lens. The lens is enveloped in a suspensory capsule, to which is attached the ciliary muscle. The arrangement is such that when the ciliary muscle is contracted, its tension upon the lens is reduced, and the lens, in virtue of its own elasticity, assumes a relatively globular form (appropriate for the focusing of near objects); while, when the ciliary muscle is not contracted, it lies in such a position that its lateral tension tends to flatten the lens, and hence to focus the system for distant objects (Helmholtz).

J. W. B.

**Hygiene of the Eye.** — Since the eye is the organ of sense most used by school children, school hygiene is especially concerned with the health of this organ and its condition of refraction. In the normal condition the antero-posterior diameter is such that parallel rays of light are brought to a focus on the retina. This condition of refraction is called *emmetropia*. Deviation from this is called *ametropia*. Errors of refraction are roughly divided into three kinds: (1) *Hyperopia*, where the antero-posterior diameter of the eye is too short and parallel rays of light striking the cornea are brought to a focus behind the retina, that is, the eyeball is too shallow. (See HYPEROPIA.) (2) *Myopia*, where the antero-posterior diameter is too long and parallel rays of light are brought to a focus in front of the retina. (3) *Astigmatism (q. v.)*, where there is an error in the refracting surfaces, either the cornea or the lens, usually the former.

Normal activity of vision usually depends upon the integrity of the visual organs, the condition of general physical health, and the condition of refraction of the eyes. In some cases, however, there is weakness of vision due to defect or disease where there is no error of refraction. This is called *amblyopia*.

The standard usually assumed for normal acuity of vision is the ability to read the standard Snellen type at a distance of twenty feet. This ability is represented by 1 or  $\frac{20}{20}$ , or, reckoned in meters,  $\frac{6}{6}$ . Snellen adopted this norm as the standard representing normal acuity of vision, but the standard is a conventional one. Stocker maintains that 1.25 should be taken as representing normal acuity of vision. As a matter of fact, he maintains that the acuity of vision most usually found among children is 1.50. In any case this is what he found in his investigations: 998 eyes among the boys, 972 eyes among the girls had a visual acuity of  $1\frac{1}{2}$ , while only 232 eyes among the boys and 238 among the girls had a visual acuity of only 1.

The errors of refraction have been studied in hundreds of thousands of school children, and very significant results have been obtained. The eye of the child at birth is undeveloped. As a rule it is an hyperopic eye. After birth development proceeds gradually, and while we do not know just at what age the eye normally becomes emmetropic, investigators have often found that at the beginning of school life more than half of the pupils have hyperopic eyes. In the later grades the majority of eyes have become emmetropic, or passed through this stage and become myopic. The number of children with defective vision varies greatly according to different investigators. The number found depends on the fineness of the methods of testing used. Some investigators have found as many as ninety-seven per cent of all children with refractive errors of some kind, and probably few, if any, absolutely emmetropic eyes can be found. If, however, we consider the number that have such a degree of refractive error that it interferes with school work, the number is still large. American investigators with ordinary tests have usually found from 10 to 30 per cent of school children with defective vision. German investigators have usually found from twenty to forty per cent, although in many instances a much larger percentage. In England somewhat different results have been found from those in Germany. Tests have been made in London of perhaps half a million children under the able supervision of Dr. Kerr. On an average ten per cent of the children were found to have vision which is bad ( $\frac{6}{15}$  or less) when tested by the teachers under the ordinary conditions of life. (*London Reports*, 1905, p. 34; 1909, p. 56.)

The sex incidence of refractive error found in London is noteworthy. Girls account for

nearly seventy-eight per cent of Mr. Bishop Harman's hospital cases, and in the school returns seventy-five per cent of the children with poor or bad vision are girls. "The causes for this divergence in visual acuity in the sexes," says Dr. Kerr, "seem purely social. There is no evidence that the eyes of boys and girls differ in growth. Whatever common eye conditions are investigated, a similar incidence is found, *i.e.* more girls than boys affected, and in each case a social influence has seemed the most constant factor. Possibly the boys play in the open air, whilst the girls are confined more to the house, and the boys, doing no needlework, have an advantage, for their accommodation muscles are in a better state of tone on account of outdoor life, and at the same time less fatigued by school work, than is the case with the girls." (*London Report, 1909, p. 57.*)

Prolonged use of the eyes for near work is generally considered one great cause of myopia, or at least an aggravating condition; and many writers seem to consider the school the chief causal factor in producing eye defects. Cohn, in his classic study of ten thousand children in Germany, some forty-five years ago, showed a very marked increase in the number of myopic pupils from the lower to the higher grades, and these and similar results have usually been accepted as showing the influence of the school. The evidence is by no means satisfactory, because, according to the view of Stilling and others, the myopic condition might have developed anyway, whether the children had attended school or not, on account of innate peculiarities of the eye. Other sources of error are also involved. For example, myopic children, being handicapped in outdoor activities, become more interested in books, and tend to remain in the school. Hence a large percentage of bright pupils are often found among those with defective vision. Recent studies have apparently demonstrated that conditions of refraction and acuity of vision are inherited. There may, however, be errors of refraction due to other causes that occur incidentally to individual growth, or that are acquired; and it is possible that a number of causes may combine to produce such defects.

The question whether a given degree of refractive error should be corrected by lenses or not is always an individual one, depending largely on the general physical health, the condition of the eye, and the like. Adequate examination and the advice of a competent oculist should always be obtained.

Certain diseases of the eye concern the school. Among these are the various forms of conjunctivitis. This disease is an inflammation of the mucous membrane connecting the eyeball and the lids of the eye. Children suffering from this should be referred to the school physician or school nurse, where such

officers are in attendance. The ordinary form, mere hyperæmia, is not contagious, but true conjunctivitis, of which there are several forms, is contagious, and epidemics are not rare. The most dangerous form is trachoma. (See TRACHOMA.) This is contagious, and investigations in New York City indicate that in certain schools of a large city it may be very prevalent and that the greatest care must be taken to avoid the spread of the disease. In New York City the cards for health inspection contain rubrics both for conjunctivitis and trachoma. The school nurses are not allowed to treat the latter disease, but if treatment is not provided by the parents, they must visit the home and explain the need of medical care. The danger of infection in this and other more serious eye diseases makes cleanliness imperative, and the use of individual towels should be required. Medical inspection for this and the other eye diseases is essential.

Specially important for the hygiene of the eye is suitable illumination of the schoolroom. (See LIGHTING.) The larger part of the light should come from above or from the left of the pupil; the ratio of window surface to floor surface should be one to five; the illumination of the darkest desk on the darkest day should be at least ten meter candles; the light should be, if possible, diffused sunlight; there should be no glare from surrounding buildings, from shining surfaces in the schoolroom, or from glazed paper, or the like, and there should not be great diversity in the amount of illumination. Hence there should be means of regulating the amount of light by curtains and the like. It should be remembered that the amount of light varies inversely as the square of the distance, not directly as the distance, from the source of illumination. Regard for this law of physics is important, not only in the lighting of schoolrooms, but in the case of home study with artificial light. The iris has an important function in regulating the amount of light that comes into the eye. In case of a bright light the iris diaphragm contracts, reducing the size of the pupil and shutting out much of the light. With dull illumination the pupil enlarges, allowing a larger amount of light to enter the eye. To a certain extent the iris equalizes the amount of light that enters the eye. Ruling out other factors the pupil expands inversely as the square of the illumination. Hence, if the amount of light is increased twenty-five fold, the amount falling on the retina is increased only five fold. The diversity in the illumination, however, is sometimes so great that it is impossible for the iris to regulate it adequately. The great variation in illumination likely to occur in our schoolrooms is shown by tests made by Professor Basquin, of Northwestern University. This investigator found that the amount of light coming through a square foot of clear glass in the roof at nine o'clock in the morning was

only 67 per cent of the amount at midday, that at 4.30 P.M. only 27 per cent of that at 12.30. Also the variation during the different months of the year was very great, December having but 18 per cent the illumination found in June. These facts show the importance of ample illumination and of suitable curtains, and the like, for regulating the amount of light.

In the hygiene of the eye the following adaptation of the rules in the military schools in Germany is applicable in the public schools. (1) There should be such a division of instruction that the eyes will never be used longer for near work than half or three quarters of an hour without interruption. Proper alternation of work and rest is to be provided for. (2) There should be frequent exercise in looking at things at a distance in order to relieve the eyes. (3) There should be much movement in the outdoor air, gymnastic plays, for example. (4) Reading by unsatisfactory light, especially at twilight, should be avoided. (5) The pupils should take a proper position in reading and writing. The eyes as much as possible should be kept at a distance of at least twelve inches from the work. (6) Spectacles should be used only by order of a physician. (7) The near-sighted pupils should have their place in a class allotted to them with due regard to the condition of their eyes. (8) The light in reading, writing, and drawing should come from the left or from above the pupil, and the object should be completely lighted. (9) School instruction by artificial light should be avoided as much as possible; when it cannot be avoided, then reading and writing should be reduced to a minimum and drawing omitted altogether. (10) A large handwriting should be required, the height of the small letters amounting to at least three millimeters. The vertical or nearly vertical Roman script should be specially used. (11) The use of writing books with a network of lines should not be permitted. (12) Tight clothing about the neck should be avoided while reading, writing, or drawing.

Dr. Ziegler has advocated eye gymnastics as especially important exercises for preventing myopia. The exercises that can be used have been described by him somewhat in detail. His principle is that the eye can be trained just as well as the muscles of the body. This eye gymnastics embraces looking exercises, judgment of distances, and orientation.

While the result of recent scientific studies is to indicate the importance of heredity and other factors rather than the school in the production of eye defects, the emphasis can hardly be put too strongly on the hygiene of the eye, cleanliness, care of the general health, and periodic tests by competent persons. Eye-strain is the cause of many serious symptoms, headache, dizziness, indigestion, nervousness, and the like. The handicap to school work is often serious. The improvement from the

correction of the eye defects in individual cases is often a revelation to teachers.

The specially important things demanded by school hygiene are the following: (1) Tests of the eyes of all school children once a year by teachers and competent oculists. (2) The correction of errors of refraction by expert advice. (3) The observance of the well-accepted rules for the hygiene of the eye. W. H. B.

See ASTIGMATISM; HYPEROPIA; MYOPIA; READING; LIGHTING; TRACHOMA.

**Movements of the Eye.** — The eye muscles rotate the eyeball within the head in such a way that images or objects at the right or left can be projected upon the retina; furthermore, the two eyes can converge upon the same object, whether that is near at hand or far away. (See CONVERGENCE.) Many abnormalities in eye movements arise as a result of lack of exact symmetry in the muscles controlling the eyes. Squinting results as an extreme type of this kind of lack of symmetry. The pathology of eyestrain has not been given the attention which it deserves in education. Many persons are subjected constantly to the necessity of excessive contraction of one or more of the ocular muscles in order to converge the two eyes properly. This induces fatigue, and often leads to extreme exhaustion, and other consequences which are far-reaching in their significance for personal health and behavior. In psychology, the eye movements have been much emphasized as significant in explaining the processes of visual perception. Whether the eye movements supply independent sensations or not has been a subject of vigorous discussion. The inner muscular adjustments, involving chiefly the lens (see ACCOMMODATION), are not usually regarded as eye movements in the proper sense of that term.

C. H. J.

**Vision, Tests of.** — The stock test of vision as administered in schools consists of a simple determination of capacity to read test types (usually of the Snellen pattern) at a distance of twenty feet. While this test is better than none at all, it fails to detect hyperopia (oversightedness), which has, in some respects, more serious and far-reaching consequences than myopia (short-sightedness), and it only indirectly reveals the presence of astigmatism.

The test here recommended, which follows, in the main, the suggestions of the American Ophthalmological Society, is designed to remedy this insufficiency. The examiner needs a test card for acuity, a test card for astigmatism (preferably Verhoeff's chart), a simple trial frame, two  $- .75$  D. and two  $+ .75$  D. spherical lenses (48-inch focus, English system), and one blank disk. (Two pairs of cheap spectacle frames, fitted the one with the convex, the other with the concave lenses, may replace the trial frame and test lenses.) Place the test type on the wall or stand, on a level with the pupil's eyes, in a strong, even illumina-

tion (though not in direct sunlight), at a distance of twenty feet (six meters) from the pupil. Note any indication of soreness or inflammation of the eyes, and ascertain whether the pupil suffers from frontal or occipital headache after using the eyes for near work, whether he has been previously examined and with what result, whether he has ever worn glasses, and why, if this is the case, they have been discarded. Adjust the trial frame. Place the solid disk before the pupil's left eye (or hold a card before it), and instruct him to keep both eyes open. Find the smallest sized line of type in which at least three fourths of the letters can be read. (Most children need urging and encouragement to induce them really to do their best.) Record the result. Whatever this may be, always try next the effect of the +.75 lens. If the eye is emmetropic (normal refraction), vision will be somewhat impaired. If vision is not impaired or is somewhat improved, the eye is *hyperopic*. If, in the first test, vision is 1 or  $\frac{2}{3}$ , and if, in the second test, vision is impaired by the convex lens, try the effect of the -.75 lens. If vision is now improved, the eye is presumably *myopic*.

If either hyperopia or myopia is indicated by these tests, or if headaches or inflammatory conditions indicate eyestrain, replace the test type by the astigmatic chart, and ask the pupil whether one or more of the radiating "wheel spoke" lines seem to him sharper or blacker than the others. If he answers in the affirmative, *astigmatism* is present. This result may be confirmed by causing the pupil to move his head from one side to the other, in which case the location of the blacker lines should shift with the movement. The degree of astigmatism may be roughly estimated by the positiveness and readiness of the pupil's answer; its axis may be determined approximately by his designation of the blackest line or lines. It must be remembered that astigmatism may exist alone or in conjunction with either hyperopia or myopia.

If the vision is subnormal, but no form of ametropia (hyperopia, myopia, or astigmatism) can be demonstrated, the defect may be ascribed to *amblyopia* (weak sight). Place the blank disk before the right eye, and proceed similarly to test the vision of the left eye. Teachers should never prescribe lenses on the strength of these tests, but should refer children whose eyes are presumably defective to a competent specialist.

Tests for *muscular imbalance (heterophoria)* are only rarely undertaken in school examinations, though the Maddox rod and the Stevens stenopaic lens afford simple devices for the purpose. Manifest disturbance of the visual axes (strabismus, squint, heterotropia) should, of course, be recorded, particularly in testing the vision of young children, since these deficiencies must be taken in hand at an early age, if they are to be corrected by the oculist.

Tests for *color blindness* are, perhaps, equally rarely undertaken, though they have considerable pedagogical and sociological significance. A scientifically satisfactory test of color blindness which shall detect color weakness and other anomalous forms of color vision as well as the usual red-green blindness, requires materials or appliances, such as the Nagel tests, that are not on sale save to physicians or psychologists, and requires, also, some technical acquaintance with the psychology of color blindness. But the well-known Holmgren colored worsted test is easily administered, and valuable so far as it goes. In conducting it, either the full or the abbreviated procedure may be followed. For the first remove the three large test skeins, — pale green, red, and rose, — and scatter the remaining skeins over a light gray cloth or paper. Ask the pupil to select all the skeins that resemble the pale green test skein, which is handed to him first. Explain that there are no two skeins alike, and that an exact match is not required. If hesitation appears, or if grays, browns, and reds, as well as greens are selected, continue the test by the use of the rose skein. The typical red-green blind will then select some blues and purples, less often grays or greens. Finally, the red test skein may be used, though many color-blinds make no errors with it, on account of its strong saturation. Preserve a careful record of the skeins selected by pupils who deviate in any particular from the normal. For the second, or abbreviated procedure, place irregularly on the cloth four green skeins and eight "confusion" skeins of gray, brown, and pink. Give the pupil the pale green standard, and require him to pick as rapidly as possible four skeins that match the test skein (in the sense above described). If this cannot be done within four or five seconds, or if mistakes occur, test further by the full procedure.

NOTE. — The appliances mentioned above may be bought from any well-equipped dealer in optical goods, who will also import the Nagel color blindness testcards for those to whom they may be sold. More explicit instructions for conducting these tests, together with typical results and conclusions, will be found in Whipple, *Manual of Mental and Physical Tests*.

**EYE AND EAR MINDEDNESS.** — It is a well-known fact that persons vary widely in the efficiency with which they can use the eye as compared with the ear. This difference has to do in part with the mere keenness of the sense organ as such, *e.g.* in seeing or hearing objects and sounds at a distance, in part with the retention in memory of information gained either through the eye or the ear. Psychological observation also tends to indicate that in some persons thought processes of a rational kind are carried on sometimes by means of visual material and sometimes by means of auditory material. There is with some individuals a marked preference for one of these forms of thought material or imagery, as compared with the other. These distinctions suggest three headings under which the matter will accordingly be treated. (1) Keenness of sensations; (2) efficiency of memory; and (3) relative value as material for reflective thought, and thus for the control of conduct.

1. Two general causative influences may produce a preference for the use of the eye or the ear as end organs of apprehension, (*a*) organic defect in one of these senses, as contrasted with normality in the other; or normality in one as contrasted with hypersensitiveness in the other; and (*b*) organic conditions of the brain favorable to one sensory region as compared with the other. For example, an individual who suffers from deafness in any degree is quite certain to make every possible use of vision and the other senses, rather than to rely upon auditory experience. On the other hand, an individual who may enjoy extremely acute vision because of the extraordinary perfection of the structure of the eye, may evince a preference for that mode of apprehension, even though hearing is normal. There are, however, abundant instances of individuals who possess a distinct preference for sensations of one or the other variety in whom no explanation based upon the mere structure of the sense organ appears to be adequate. Such persons are said to be more interested in things which they see, for example, than in things which they hear. Such preferences are presumably to be connected with differences in brain organization, which result in a readier response to one kind of stimulation than to the other.

One must recognize within this range of differences a number of subordinate variations. For example, in the case of auditory sensations an individual may be relatively insensitive to sounds of all kinds, so that to attract his attention or to make him understand readily requires speaking in a tone of voice louder than is necessary in ordinary conversa-

tion. As contrasted with this type of defect, which is a common consequence of catarrhal troubles and of many febrile diseases, is to be mentioned defect in the discrimination of tones, as in the case of persons who cannot reproduce a simple melody, who cannot discriminate from one another adjacent tones in the musical scale. Many individuals are able to make relatively rough discriminations, who are nevertheless markedly inferior to the normal person, who is capable of discriminating much minuter differences in pitch. The medical specialist often meets with individuals manifesting a type of disorder leading to the appearance of so-called "tone islands." The patient may, for example, be unable to distinguish any pitch differences in the five or six notes lying in the middle of the piano scale, although he is substantially normal in his power to discriminate tones in the remaining portions of the scale. Again, individuals may enjoy relative normality of hearing as regards the points already indicated, while they are somewhat defective in their power accurately to localize the source of sounds. This type of difficulty is generally associated either with total or with partial deafness in one or both ears. Evidently, however, a defect in hearing which affects either the power to localize or the power distinctly to understand sounds of normal intensity will exercise a discouraging influence on the use of the ear as an organ of apprehension. Defects of the type mentioned second, *i.e.* those concerning the discrimination of the pitch of tones, will obviously militate against the appreciation of, and participation in, music of most kinds.

In the case of vision we meet with a similar series of defects. There may, for instance, be malformations of the eyeball and its contents, or of the muscles of the eye, leading to indistinct or painful vision. The troubles which the optician has to deal with are chiefly of this character, and need not be described in detail. Over against these are deficiencies in color vision, with color blindness as the extreme representative, and with various degrees of imperfection in the power of color discrimination as intermediate between this extreme and normal color vision. Evidently a person suffering in any serious degree from one or more of these forms of visual defect is likely to be influenced toward the cultivation of all available sensory substitutes for vision. This is at least true of the serious defects in the distinct vision of objects. It is much less certainly true of the case of color blindness which in its more serious forms necessarily precludes any successful cultivation of the æsthetic interest in color, even though it leaves untouched the normal sensitiveness to the visual objective world. As a matter of fact, color blindness is very apt to result in augmenting the sensitiveness to other aspects of the visual world, such as form and brightness.

2. Certain peculiarities of the memory process will now be dealt with. It will be understood that memory stands in such relations to the sense activities that the points just rehearsed bear inevitably on the memory case. In considering the memory processes, there must be distinguished (*a*) those influences which affect the quickness of learning or impressing, (*b*) those which concern the permanency of retention, and (*c*) those which have to do with ease and promptness of recall. It is a matter of common observation, which is well supported by experimental research, that some persons can memorize a given material more quickly by seeing it than by hearing it; and the converse case is often met with. Evidently such differences may have their explanation in organic variations either in the structure of the sense organs or the brain, as indicated in the paragraphs preceding; or they may find their explanation in terms of habituation and practice, the individual for one reason or another having disciplined one mode of learning more fully than the other. So far as concerns permanency of retention, there is no reason to believe that material impressed upon the ear is either better or less well remembered than that impressed upon the eye. At least this is true so far as concerns any universally valid principle. Particular individuals undoubtedly retain better in one way, and other individuals retain better in the other way. In learning verbatim, the general fact is that material which requires longer for its original learning is retained better than material more easily learned. But there are many exceptions to this, and in any case sufficient repetition will stamp in any material whatever with a high degree of permanency. The same thing is true as regards ease and promptness of recall. There is no reason to think that one type of material is *per se* better than any other.

At this point the reader needs to be safeguarded against a very common fallacy. Psychological writers have often assumed that because one learns most readily through the eye, for example, that one therefore *recalls* his experiences primarily and dominantly in visual imagery. This may or may not be the fact, but it is certainly not in any sense universally true. It is equally untrue that one who learns most easily through the ear can be safely inferred to recall his experiences in auditory form.

Why one method of memorizing should be preferred to another may perhaps be attributable in part to the sensory differences already mentioned, but it seems much more likely that it has to do with variations in the organization of the brain where a higher sensibility and a greater retentiveness of one region as compared with another is surely the natural thing to be expected. Habit must also play a very important part, and although the original preference for one form may have been essentially acci-

dental, if it once becomes established, it may persist indefinitely.

3. The same kinds of differences which are met with in sense apprehension and in memory also characterize the trains of imagery which constitute the basis of imagination and which are for many people the material of reflective thought. These images (the mental copies of sensations and perceptions) may be of many other kinds beside visual and auditory, *e.g.* tactual, although these two forms certainly share with motor imagery the dominating place in consciousness. It has been generally believed in recent years that in the thought processes of any given individual, some one form of imagery prevailed markedly over other forms. More recent investigations tend to show that individuals make use as a rule of several different kinds of imagery, particularly visual, auditory, and motor (some of it serving to represent *objects* and some of it representing *words*, whether as seen, heard, or spoken). These different forms of imagery are likely to be more or less intermingled in any complete chain of thinking, and some one type of imagery is almost certain to be preferred for special kinds of thought. For example, an individual may reason out simple mathematical problems almost altogether in terms of visual imagery, whereas he may be perfectly able to use auditory imagery, if he desires to recall a bit of music. He may use visual, objective imagery in solving a perplexity in a geographical problem, whereas he might use auditory word imagery (generally combined with vocal, motor imagery) in thinking out a problem in algebra or a problem in ethics. There is thus rendered possible a very elaborate shunt system in most minds, by which the several varieties of imagery available by the individual are likely to be brought into use when for any reason the commoner forms are temporarily less accessible.

In this field, also, the explanations of the individual's preferences may be sought either in the original structure of his brain, or in the accidental exigencies which may have caused him to build up his habits of thought around one kind of imagery rather than another, even though at the outset the one had been as available as the other. Observations on children lead one to believe that there is a rather strong native predisposition to certain forms of imagery as compared with others. No doubt this would be found connected with hereditary traits in most cases, provided we were in a position to command the necessary evidence.

It is not possible to say that either auditory or visual material is *per se* superior the one to the other, at least for the ordinary purposes of memory, of thought, and of the control of conduct. But it is perfectly clear that for certain aesthetic interests the matter is of first-rate consequence. To attempt to teach a child music who has defective powers of discriminating pitch, or to expect an individual to take any

serious interest in music who cannot command auditory imagery, is essentially ridiculous, and certain to issue in much hardship for the child and much futile labor for the teacher. Adequate tests on these matters should certainly be instituted in all cases where children appear to be unresponsive to such training. Similarly in the case of drawing and painting. A child who is seriously defective in distinctness of vision is not likely to be forced into the artistic use of the pencil or the brush. Nor are children who are seriously deficient in color discrimination likely long to be subjected to training in the use of pigments. Nevertheless, there are not a few cases on record in which this sort of absurdity has been practiced. It is much more likely, however, that children who are seriously defective in visual imagery should continue to be subjected to training in drawing and painting, and in such cases teachers are apt to cherish the hope that sooner or later the powers of imagery may be thus developed. We are not in a position at present to state definitely within what limits such defective imagery can be trained. But there seems no reasonable ground to doubt that certain children are born with limitations in this direction, which, practically speaking, cannot be altogether overcome, and it is certainly a matter of consequence to determine as early as possible whether or not such limitations exist.

The question is often asked whether it is desirable to attempt to train forms of imagery which the child does not naturally employ. In a practical way this inquiry may be confined to the images of vision, hearing, touch, and movement. The only reply which can be given is based upon general considerations rather than upon adequate experimental evidence. There can be no doubt that in a general way it is desirable to be able to use any of these forms of imagery at will. A mind in possession of such capacities is a richer and more flexible instrument than one deprived of some one of these avenues of apprehension and appreciation. But it may well be doubted whether in the case of a strong predisposition to specialize in one or two directions, there is any compensating advantage to be gained in return for the time and effort expended in trying to develop the unused form. Common sense would seem to indicate that the wise course would involve a serious effort to call out the missing type of response, but that, if a brief period of such discipline produced no reaction, it would be presumably unprofitable to attempt to force what the evidence would then indicate as an unnatural line of development. Moreover, it is to be remembered that most forms of practical efficiency are conditioned by the flexibility, rapidity, and accuracy of our manipulations of the materials of thought, rather than by the use of any particular kind of material. Thought functions in a vicarious way, and the most remarkable and successful results often

emanate from the use of a very circumscribed kind of material.

In conclusion, it is to be recognized that, however much we may wish to develop and train a given kind of imagery, we are at present far from possessing any confident knowledge of how to proceed to that end. Broadly speaking, the simplest and most commonly successful methods involve the use of stimulation to one or another sense organ with instructions to the subject to recall as nearly as he can the exact manner in which the stimulus looked, or sounded, or felt, etc.

**EZRA, RABBI BEN.**—See **IBN EZRA, ABRAHAM BEN MEIR.**

**FABLES.**—The term in a broad sense is applied to a great variety of imaginative stories, but it is also used in a more restricted sense to designate an animal story with a moral attached. This latter class of fables may be divided into two distinct categories: (1) Popular fables, those which are handed down by word of mouth, and have circulated among all classes of society in every age and in every clime. This category belongs to the domain of folklore (*q.v.*) (2) Literary fables, those which descend from writer to writer, and which pass from one literature to another in a written form. It is this class of fables of which an extensive educational use has been made for more than two thousand years past.

Aside from numerous references to the use of fables in the schoolroom which are to be found in classical Greek and Latin authors, there have been preserved by fortunate accidents two schoolboy slates (wax tablets), dating from the third century of our era, which actually contain the fables written at the behest of the schoolmasters. One of these was found at Palmyra in Asia Minor, and contains the text of several Greek fables; the other was found in Egypt, and gives a Latin text which has evidently been translated from the Greek.

In the early Middle Ages the fables of Flavius Avianus were commonly used in the schools as elementary reading for boys learning Latin. This practice accounts for the very large number of manuscripts of this work still extant, and for the many references to its author found in the works of medieval writers. Sometimes the fables of Romulus were used as well as those of Avianus, and in this case the name used to designate them was commonly Æsopus. Thus Otloh testified to the use of Avianus in

German schools in the eleventh century; and Egbert of Liège, a teacher in the cathedral school at that place, wrote about the year 1023 a textbook for boys learning Latin, in which he introduced a number of the fables then current in a written form. Conrad von Hirschau in the twelfth century likewise refers to the use of fables for purposes of instruction, as does Hugo von Trimberg in the next century, writing from a village near Bamberg.

Many rhetoricians and schoolmasters introduced fables in their books for beginners, and in the twelfth century Walter the Englishman assisted his royal pupil to versify the fables of Romulus in elegiacs. This collection was later a great favorite in the schools, and eventually took the place of the older collections previously employed. Transformed in various ways, its vogue lasted for some four centuries. In the fourteenth century Stephen Patrington wrote a commentary to these fables, intended to increase their usefulness in English schools; and in Italy they were supplied with an Italian commentary for the use of schoolboys. In this latter form they were frequently published toward the end of the fifteenth century and during the whole of the sixteenth. But they had also been included in a popular textbook called the *Auctores Octo*, and had thus been printed over and over again in various places, even as far off as Spain.

When in the sixteenth century La Fontaine composed his deservedly famous fables, a fresh impulse was given to the use of these stories in the schools, an impulse whose influence is still strongly felt in many parts of the world. In France they have become a regular school classic, and in Germany, England, and other countries they are still in great demand. Even in America there have recently appeared two editions designed for use in colleges and secondary schools.

In England Bewick's fables are favorites with the children, in Germany those of Wilhelm Hey, in Spain those of Samaniego. Indeed, there has been a tendency of late years to push the educational use of fables back into the kindergarten stage. For older pupils readers and chrestomathies of all sorts usually contain at least a few fables, and it is quite a common thing to find them at the very beginning of the texts printed in such books.

The fable at its best would seem to be the precipitate of century-old observation of animal traits, and as such its appeal to childish minds is at once immediate and powerful. G. C. K.

**FABRICIUS, JOHANN ALBERT** (1668-1736).—One of the ablest classical scholars in Germany at the beginning of the eighteenth century, and founder of the study of the history of classical literature. He showed marked ability as a student at school and at the University of Leipzig, where he studied medicine, theology, and literature. In 1694 he was employed by a pastor in Hamburg as assistant in his valuable library. Here he wrote the *Bibliotheca Latina* (1697), a literary history with biographical and bibliographical notes. He was ordained and was an occasional preacher in Hamburg. In 1699 he was appointed professor of moral philosophy and eloquence in that town, and refused numerous invitations from other important German universities. For a short time he was also rector of the Johanneum (1708-1711). In addition to his classical interests he was instrumental in establishing the *Teutsch-übende Gesellschaft* for the cultivation of the vernacular through translations and original works. Fabricius' most important contributions were in the field of history of classical literature. The Latin work mentioned above was supplemented in 1734-1736 by *Bibliotheca Latina mediæ et infimæ Aetatis*. His great work was the *Bibliotheca Graeca* in fourteen volumes (1705-1728). In the field of classical antiquities he issued in 1713-1716 the *Bibliotheca Antiquaria* and a new edition of Banduri's *Bibliotheca Nummaria* (1719). Besides these works he edited Sextus Empiricus, *Dio Cassius*, *Marinus de Vita Procli*, and wrote several theological works. His biography was written by his son-in-law Hermann Samuel Reimarus (*Commentarius de Vita et Scriptis Johannis Alberti Fabricii*, Hamburg, 1737.)

**FACIAL ANGLE.**—See CRANIOMETRY.

**FACILITATION.**—See HABIT.

**FACT.**—Literally, something done, effected. Since what is effected is secured, the element of assurance, of certainty, of conviction is generally implied when anything is referred to as a fact. Logically, the term "fact" is thus antithetical to idea, guess, hypothesis, theory, fancy. The distinction is thus a relative, not an absolute, one; that is to say, certain things which were once unquestionably accepted and so had the status of "fact" may after a time become doubtful, or even rejected; then they are treated as ideas, or, if entirely rejected, as

mere ideas or fictions. On the other hand, the progress of science often gives such security to what at first was a theory that it is admitted as fact. Since every genuine judgment (as distinct from a verbal enunciation of something already known) involves an inquiry, or represents "going from the known to the unknown," every judgment involves both "fact," *i.e.* something taken for granted, and "idea," *i.e.* a hypothetical meaning emphasized to reinterpret the fact. In the procedure of advancing from the known to the unknown, "fact" is the subject of judgment, the situation so far as known, while the predicate is the unknown so far as an idea tentatively and hypothetically stands for it. (See JUDGMENT.) Educationally, the problem accordingly is to utilize facts, not as ends in themselves (the gradgrind, dry-as-dust type of instruction), but as material of judgment, *i.e.* for advance into the hitherto unknown. **FACTOR.** — A positive integer that is contained without a remainder in a positive integer is called a *factor* of the latter. Thus, 2, 4, 5, 7 are factors of 140. In the older mathematics 1 was not considered a number (see UNITY), and hence it was not considered a factor of any number. The product of several factors was occasionally known as a *factus*, as in the works of Ramus and Schonerus (*qq.v.*). The broadening of the number concept and the developing of an algebraic symbolism have led to the occasional removal of some of the primitive limitations, so that  $-2$  is occasionally considered a factor of 4, although in the theory of numbers (*qq.v.*) the restriction to positive integers is still maintained. In algebra the ancient usage is followed as far as possible, but it becomes necessary to recognize other kinds of factors. Thus we say that:  $a$  is an algebraic factor of  $ax$ , although  $x$  may turn out to be a fraction;  $\frac{1}{a}$  is a factor of  $\frac{1}{ax}$  within the domain of rationality, although not within the domain of integers;  $-a$  is a factor of  $ax$ , although not within the domain of positive integers;  $\sqrt{a}$  is a factor of  $a$ , although not within the domain of rationality; and so on.

This expansion of the idea of factoring is necessary in the solution of equations. Thus to solve the equation  $x^2 - a = 0$  we may say that  $(x + \sqrt{a})(x - \sqrt{a}) = 0$ , and equate each factor to zero. We have here factored within the domain of rationality as to  $x$ , but not as to  $a$ . In elementary algebra we are likely to see more of this expansion of the idea of factor.

The subject of factoring in algebra occupied little attention in the United States until the

last quarter of the nineteenth century. It then became very popular with teachers, and was carried to an extreme from which there has of late been a decided reaction. The subject has two manifest applications: (1) to the reduction of fractions to lowest terms, and (2) to the solution of equations. As to the first, there is a decided tendency at present to limit the style of fractions under consideration to those that the pupil is liable to meet in elementary algebra. This has lessened the number of cases of factoring necessary for the reduction of these forms to simpler terms. With respect to the use of factoring in the solution of equations, it is evident that the binomial factor is the important consideration, and hence much emphasis is needed upon the so-called Remainder Theorem (or Factor Theorem, as it is sometimes less satisfactorily named), a theorem by which we determine if  $x - a$  is a factor of  $f(x)$ . From the point of view of actual use, this theorem is the most important one in elementary algebraic factoring. D. E. S.

**FACTORY, CHILDREN IN.** — See CHILD LABOR AND EDUCATION; CHILDHOOD, LEGISLATION FOR THE CONSERVATION AND PROTECTION OF; FACTORY SCHOOLS.

**FACTORY INSPECTION.** — See CHILD LABOR; CHILDHOOD, LEGISLATION FOR THE CONSERVATION AND PROTECTION OF.

**FACTORY SCHOOLS.** — A general term given to the schools which were established in England in the first half of the nineteenth century in factories or close to factories for the education of young employees. The employers in certain industries were compelled by factory acts to provide for the education of the children whom they employed. Thus the act of 1802 (42 Geo. III, c. 73), among other provisions for the welfare of apprentices in cotton and woolen mills, provided for their education during part of every working day for the first four years of their apprenticeship, and also for their religious education on Sunday. But little was done as a result of this act, and the act of 1819 made no educational provision. The Factories Acts of 1833 (3 and 4 Will. IV, c. 103), of 1841 (7 Vict., c. 13), and 1847 (10 Vict., c. 29) extended the provisions to an increased number of industries and introduced the half-time system, by which no child under eight could be employed in a factory, and children between eight and thirteen must attend school for three hours a day, if employed every day, and, if working on alternate days, then school attendance was required for five hours. Parents and employers were made liable for neglect; the employer had to pay the schoolmaster a penny in the shilling of the child's wages, and the schools were placed under the supervision of the factory inspectors.

## FACULTY

While a few of the employers took their responsibility seriously, they formed a very small minority. The majority of the schools provided under the acts were mockeries of education; not only were many of the schools unsanitary, but the teachers were utterly incapable. But these schools are important in the history of English education as elements in the development of elementary schools. At the same time, this factory legislation introduced the pernicious half-time system (*q.v.*), the abolition of which is now under consideration.

Another type of factory school is that attached to factories for the industrial and vocational education of young employees. The new type of apprenticeship in large factories which has recently sprung up involves the training of apprentices in such special schools.

**FACULTY.** — The term "faculty" is closely related to the term power, facility, capacity. Historically, the word was originally closely bound up with the Aristotelian distinction between potentiality and actuality. An acorn is an oak in potentiality, not in actuality. Actuality means the thing in full operation, in completely functioning activity; potentiality means the power of becoming the actuality. A man's faculties are thus the potentialities which, if exercised, result in specific acts and operations. A man has the "faculty" of memory, even when he is not remembering, etc. At a later period, however, the Aristotelian sense of potentiality dropped away from the term "faculty," and it was used as a causal energy to explain certain acts. The soul was fitted out with a number of ready-made faculties; thus a recollection was accounted for by referring it to a faculty of memory which produced it, and so on. When, however, mental acts had been, proceeding on this method, quite exhaustively classified, it was seen that the result was barren for purposes of explanation, since the "faculty" was simply an abstract name for exactly the things which in the concrete it was supposed to explain. In England the associational school, and in Germany Herbart, was especially active in the overthrow of this barren "faculty psychology." In education, the doctrines of ready-made faculties sharpened by exercise and of formal discipline (*q.v.*) stand and fall together.

The term was much more freely used in the earlier stages of psychology than at the present time. It was especially useful at a period when psychology concerned itself chiefly with the classification and description of mental processes. Thus, Sir William Hamilton (*q.v.*), in his discussion of mental powers (*Metaphysics*,

## FACULTY

Lecture XX), enters into an elaborate historical and critical discussion of the various faculties, and presents a complete system of subdivision of the knowledge side of experience, as follows:

COGNITIVE FACULTIES	{	I. Presentative	{ External = Perception. Internal = Self-consciousness.
		II. Conservative	= Memory.
		III. Reproductive	{ Without will = suggestion. With will = Reminiscence.
		IV. Representative	= Imagination.
		V. Elaborative	= Comparison-Faculty of Relation.
		VI. Regulative	= Reason- Common sense.

In the historical discussion by which he supports this division, Hamilton brings into sharp relief one of the difficulties of this type of consideration. He points out that St. Thomas "held that the faculties were distinguished not only from each other, but from the essence of the mind" (page 272). The view here referred to was a very easy one to fall into. When a faculty, such as memory, is impaired, and another, such as perception, is apparently undisturbed, it is very natural to distinguish the faculties from consciousness in general, as though the faculties were separate limbs or members of the mind.

In contrast to St. Thomas, Henry of Ghent held "that the faculties are really distinguished from each other, but not from the essence of the soul" (page 272). Hamilton quotes with approval, as expressing his own view, a passage from Addison: "That which we call the faculties of the soul are only the different ways or modes in which the soul can exert herself" (page 268).

The foregoing statement of the doctrine of faculties could be indefinitely expanded by referring to other systems of classification of mental powers. One system of such classification which is popularly known is that employed by the pseudo-science of phrenology. Combative-ness, reverence, perception of form, of number, and of color, are here regarded as separate members of the conscious whole. All of these systems of classification are open to at least two fundamental objections. First, they distinguish classes of mental powers which are in no sense mutually exclusive. Thus, to distinguish between memory and imagination is to cause endless confusion, for it is altogether impossible to treat of our concrete experiences without recognizing that any real experience is at once conservative, reproductive, and representative. Second, when explanatory psychology attempts to account for mental processes, the faculties prove to be wholly fictitious units. Perception of form is inexplicable without reference to memory, and reverence is not seated at a point in the nervous system which differs from that at which imagination is located.

Wundt makes a vigorous attack upon faculty psychology as follows: "Class concepts were formed. . . . Such concepts are, for example, sensation, knowledge, attention, memory, imagina-

tion, understanding, and will. They correspond to the general concepts of physics — such as weight, heat, sound, and light. Like those concepts of physics, the derived psychological concepts . . . contribute nothing whatever to the explanation of the facts. Empirical psychology has, however, often been guilty of confounding this description with explanation. Thus, the *faculty psychology* considered these class-concepts as psychical forces or faculties, and referred psychical processes to their separate or united activity." (*Outlines of Psychology*, page 12.)

When psychology began to explain mental processes as well as describe them, the older classifications quickly gave way to new types of consideration. Sensory processes and motor processes came to be recognized as of cardinal importance because of their relation to physiological structures. The scheme of psychological classification (*q.v.*) underwent a radical change. There is, to be sure, need of a system of classification now quite as much as at earlier stages of the science, but this classification is dominated by explanatory rather than by purely descriptive motives. For example, attention is not treated as a separate entity in consciousness, because it is a general fact of all experience. Attention is a term which is very useful in description and discussion, but it is not a separate limb of consciousness. The term "faculty" has been very largely dropped by careful writers because of the many discussions which have centered about it, and because of the implication which it might introduce into psychological and educational treatments of present-day topics. Nevertheless, there is in current discussions a certain tendency to commit some of the fundamental fallacies of the earlier faculty psychology. The opponents of the doctrine of formal discipline, in their efforts to show that there is no such general training as has frequently been assumed, are subdividing consciousness into separate and distinct modes of activity, hardly less rigid and atonic than were the faculties. Thus, the perception of squares has been regarded as so highly specialized a function that it must not be confused with perception in general. The attack upon the general faculty of perception has thus led to a belief in many faculties of perception. These many faculties which might now be designated faculties for perception of squares, circles, triangles, etc., are separate and distinct in their character, and in their training. Education must cultivate each in its order, we are told, or the individual will suffer from the atrophy of his special faculties. This modern form of faculty psychology is quite as objectionable as the older form. The only rescue from this subdivision of consciousness is through a thoroughgoing functional treatment of mental life. (See *PSYCHOLOGY, FUNCTIONAL*.)

When consciousness is recognized as an organized system wherein all of the powers are what they are by virtue of types of organiza-

tion, there will be no tendency to break up mental life into faculties, or separate modes of activity.

The separate modes of activity may continue to be distinguished and designated for purposes of description, but explanatory science will dominate even descriptive phases of the science.

**FACULTY PSYCHOLOGY.** — See *PSYCHOLOGY, FACULTY*; *FACULTY*.

**FADS, EDUCATIONAL.** — A term of criticism and sometimes of derision, applied to those features or parts of school work which seem to be of an ephemeral nature or of little permanent value, and which are being urged for adoption, or, having been adopted in some places, are apparently being overemphasized. Just what constitutes an educational fad depends much upon the individual point of view. Often the new and apparently impractical ideas of one decade are accepted as worthy additions to instruction by the next. Froebel and the kindergarten, and Horace Mann and his idea of normal training, were once ridiculed and regarded as visionary, and those who advocated their introduction were declared to be following educational fads. The same was true later on of manual training, domestic science, nature study, the high school, technical training, and other new subjects. To some an educational fad is anything except the seasoned and well established fundamentals of education, such as reading, writing, spelling, arithmetic, geography, and grammar. By such persons such subjects as music, calisthenics, manual training, and domestic science are still classed as fads. To others, who accept these newer subjects as substantial additions to our school curriculum, other newer proposals, such as directed play, vacation schools, vocational training, medical inspection, health supervision, and parental schools are in the nature of fads. With still others the term is used in a still more restricted sense, and is used to designate only unphilosophical

sophical and unpedagogical attempts to satisfy popular clamor or the passing fancy of the time. The term is commonly applied to new ideas and proposals, and what is at first termed a fad and often ridiculed is not infrequently accepted later and incorporated as a part of our regular school work. E. P. C.

**FAGGING.**—It is strange that, while fags and fagging occupy so large a space in all school literature in England during the last century, whether in lives of famous men, school histories, or official reports of commissioners, not a trace of it can be found before the last quarter of the eighteenth century. To read some writers one might suppose that the institution of fagging, that is to say, the making of small boys do menial offices and dirty work for big boys, was the essence of the so-called "Public School" system on which England prides itself, and that it had descended from immemorial antiquity and made "Englishmen what they are," whatever that might be. In point of fact, it does not seem to be heard of in literature before the last quarter of the eighteenth century. In the two most famous documents which described school life, the *Consuetudinarium* at Eton prepared by the Headmaster William Malim for a royal commission in 1561, and *De Collegio seu potius Collegiali Schola Wiccamica Wintoniensi*, which used to be attributed to Christopher Johnson, the headmaster of Winchester about 1560, but which has been shown to have been written about 1650, there is no hint of fagging. The fagging system, which is really nothing more than the conversion of small boys into servants to big boys, is popularly supposed to be connected with and part of the prefect or monitorial system, of the self-government of which so much is said, but which is the government of young boys by elder boys. The prefect system (*q.v.*) can be traced to about the time of William Wykeham, who in the statutes of Winchester College in 1400 provided that "in each chamber (of twelve boys) there should be at least three scholars of good character more advanced than the rest in age, sense and learning to superintend the studies of their chamber-fellows and diligently correct them and to inform the Warden and Magister Informator of their morals, behaviour, and advancement in learning," so that the defaulters may be duly punished. A similar provision appears for the fellows of New College, and was taken in turn from a similar provision in the statutes of Merton made in 1274. But it will be noticed that while in later days the prefects themselves inflicted punishment, in 1400 and in 1650 the prefects

were not magistrates, but police constables; they did not punish offenders themselves, but only reported them to the master, who alone inflicted the penalty. There was of course no necessary connection between this power of reporting and the power of compulsory service. Nor was there scope for it. In fact, in 1650, as in the statutes made by Queen Elizabeth for Westminster School in 1560, all the boys were under one common servitude. At Westminster, "prayers finished they all make their own beds. Then each shall take any dust or dirt there may be under his own bed and carry it to the middle of the chamber, and these shall be swept up into one heap and carried out by four boys appointed by the prepostor." In the same way at St. Paul's, Colet in 1518 provided for a "pore scoler" being appointed to sweep the school, but he was paid for doing so with the admission fee of 4*d.* each paid by new boys. So, too, another "pore childe of the scole," looked after the latrines and had the "avayle of the urn" for it. This was all in accordance with the usual practice, under which the sons even of lords and earls went as "henchmen" or servants into the household of the king or the chancellor or archbishops and bishops, securing their education at the same time, but waiting at table and performing menial offices for their masters. The Prefect of Tub (*Prefectus olle*) at Winchester in like manner had to collect the fragments and crumbs and broken meats in hall and place them in a large tub, which still stands in hall, whence they were distributed to the poor; and he dined with the servants after the others had done. The choristers too, sixteen in number, who did their lessons in school with the rest, and most of whom were afterwards admitted as scholars,—at Eton the choristers of Eton and King's had even a statutory preference for being admitted as scholars,—waited on the scholars. It was not till about 1711 that, at the instance of the Bishop of Winchester as visitor, the scholars were relieved of what he called the foul and servile office of making their own beds, and in 1778 it was ordered that any beer wanted in chambers at proper times was to be carried down by the bed makers and not by any of the boys on any pretense whatsoever. The junior boy at each "end" in hall was, however, to pour out the beer for the rest. Even then the prepostor of the hall was to "accuse" those absent, and not punish them himself.

But from 1775 onward the fagging system was in full swing. It probably came into existence with the organization of games and the practice of extra meals. The hour for going to bed as late as 1650 was eight, and even in 1778 the juniors were ordered to be in bed at half past eight and the prefects at nine. Supper (*merenda*) was provided in hall, and there was no scope for extra meals. There were no organized games much before 1775. Gray's *Ode to Eton* in 1747 speaks of cricket, football, and hoops, but not for matches. A cricket song written by a

Winchester scholar, George Huddesford, in 1769, was not for the school, but for the Hambleton Club, and in another poem written about the same time on Whitsuntide he celebrates cricket as a game played in the summer holidays, which then began in June, not as now at the end of July. It was the organization of games and of meals which produced fagging and caused infinite misery to generations of small boys. To have to prepare sausages and toast for breakfast was no great hardship, but to have to get ready coffee or cocoa or hot beer at night and to clean the pots and pans and cups afterwards; to have to provide hot water for washing, was a real hardship, especially when every breakage was probably punished with a spanking. Mr. Oscar Browning, in his *Reminiscences* (1910), says that it used to be common complaint against small collegers at Eton that they were dirty and untidy, and he asks how they could be otherwise with the tasks they had to perform, with chapped hands cleaning pots and pans, oiling cricket bats, even shining boots. Then in play time, instead of enjoying themselves by themselves, the boys had to long-stop and field at cricket, and to be admonished for mistakes even with a cricket stump; at football to stand about and kick in the ball; at rackets in the open courts of those days, to stand around and field the ball. With a good-tempered prefect or preceptor it was not so bad, but the bad-tempered or the bully certainly predominated, and thus made life a burden to the unhappy junior. Meanwhile, not only the authorized seniors, but unauthorized big boys low down in the school, naturally took to fagging on their own account. *Tom Brown's School Days* shows the quarrels that arose then between the lower and the fifth-form boys as to the right of the latter to fag them, and to kick them if they did not obey. At Eton school 350 boys had the right of fagging the rest. The "old boy" was very fond of bragging about the miseries he endured and the merits of the Spartan discipline, and so forth. It was all very well, looking through the glamour of years. But numbers of boys broke down under the system, many had their spirits crushed, and others had cruelty instilled into them. The same people who advocated flogging in the army and the navy and the hanging of men for stealing 6s. 8d. in a dwelling house supported unlimited fagging and its accompanying unlimited physical violence. But in all the great schools fagging has, since 1870, now been reduced to a minimum, and the violence accompanying it forbidden. The result is that the small boy now enjoys school life instead of hating it; his learning has increased his strength and spirit are improved and not diminished; and his morals and manners have not suffered, but developed.

A. F. L.

**FAIRCHILD, EDWARD HENRY** (1815-1889). — College president, graduated at Ober-

lin College in 1839. For several years he engaged in educational work among the negroes of Ohio. He was a professor in Oberlin College from 1853 to 1869, and president of Berea College from 1869 to 1889.

W. S. M.

**FAIRCHILD, GEORGE THOMPSON** (1838-1901). — College president and apostle of agricultural education, graduated from Oberlin College in 1862. He was professor in the Michigan Agricultural College (1865-1879), president of the Kansas Agricultural College (1879-1897), and vice-president of Berea College (1898-1901). Author of numerous papers on agricultural education and rural problems.

W. S. M.

**FAIRCHILD, JAMES HARRIS** (1817-1902). — An ardent advocate of the higher education of women, graduated at Oberlin College in 1838. He was a professor in that institution for twenty-eight years (1838-1866), and president of the college from 1866 to 1889. His educational writings include *Cocducation of the Sexes* and papers on the education of women.

W. S. M.

**FAIRMOUNT COLLEGE, WICHITA, KAN.** — Opened in 1892 as a preparatory school, and organized as a college in 1895. Academic, collegiate, and music departments are maintained. Candidates to the college are admitted on certificate of an accredited high school or on an examination, the requirements for which are equivalent to fifteen units. There is a faculty of nineteen members.

**FAIRY STORIES, VALUE AND PLACE OF IN EDUCATION.** — See FOLKLORE; STORY TELLING.

**FAIRY TALES.** — See FOLKLORE; MYTHS; STORY TELLING.

**FALK, JOHANN DANIEL** (1760-1826). — The founder of the first German Child-Rescue Institution (*Rettungshaus*); born in Danzig. After leaving school at the age of ten, he was enabled, through the intervention of one of his teachers, to take up his studies again; and in 1791 he entered the University of Halle, where he devoted himself to the study of philology and of the Kantian philosophy. Having become known as an author, chiefly of satirical poems, he moved to Weimar in 1797, where he gained the friendship of Wieland, Herder, and Goethe. In 1813 he founded the "Society of Friends in Need," in order to alleviate the distress into which the country had fallen in consequence of the Napoleonic wars, and undertook the care and education of orphaned and neglected children. The most talented of these were trained by himself, with a view of their becoming helpers in what he called the work of "home mission" (*Innere Mission*). With the aid of his pupils, he personally erected a building in which he could provide for about two

hundred children. The children were kept there until they could be apprenticed with artisans; some were even sent to the teachers' seminary or the Latin school; these, in turn, had to instruct the younger children. For girls he instituted a sewing, spinning, and knitting school. After his death the institution was taken over by the State (1829), and it still exists under the name of *Falkisches Institut*.

Falk's pedagogic ideas are eminently sound and practical. The formation of a moral and religious character he considers as the most important aim of education. He emphasizes the necessity of instruction in the mother tongue and its literature, in history, science, and art. The rescue work which he started was taken up on a larger scale by Wichern, who, in 1848, founded the *Innere Mission*, a large organization for evangelical and social effort throughout Germany.

Falk's satirical works were published in 1826 in seven volumes. Of biographical interest are the two books: *Geheimes Tagebuch, oder mein Leben vor Gott (Secret Diary, or My Life before God)* (Halle, 1898); and *Goethe aus näherem persönlichen Verkehr dargestellt (Goethe described from close personal intercourse)* (Leipzig, 1832). His pedagogic ideas are contained in a pamphlet, published in 1821, entitled: *Von dem Einen, was unseren Gymnasien und Volksschulen in ihrem jetzigen Zustand nützt (The one thing necessary for our gymnasiums and public schools in their present condition)*. F. M.

**FALKLAND, VISCOUNT LUCIUS CARY** (1610?–1643).—Statesman and author; of importance in the history of education from his keen sympathy with the Oxford University men, who by discussions on questions connected with philosophy and experimental subjects became the pioneers of the movement which led to the formation of the Royal Society (*q.v.*). The *locus classicus* on the Great Tew group is in Lord Clarendon's *History of the Great Rebellion*: "His [Lord Falkland's] house being within ten miles of Oxford, he contracted familiarity and friendship with the most polite and accurate men of that university; who found such an immenseness of wit, and such a solidity of judgment in him, so infinite a fancy, bound up by a most logical ratiocination, such a vast knowledge, that he was not ignorant in anything, yet such an excessive humility, as if he had known nothing, that they frequently resorted and dwelt with him as in a college, situated in a purer air; so that his house was a university in a less volume, whither they came not so much for repose as study, and to examine and refine those grosser propositions, which laziness and consent made current in vulgar conversation."

Lord Falkland's wife was Lettice (1611–1648), daughter of Sir Richard Morison. After Lord Falkland's death, she gave herself up to private religious devotions, family prayers, singing of psalms, catechizing of children and domestics, visiting of poor neighbors, to whom she would sometimes read religious books while they were employed in spinning. For the poor children she erected a school where they were to be taught both to read and to work. She projected a college for the education of young gentlewomen and for the retirement of widows; to be for women "as colleges and the Inns of Court and Chancery are for men" in several parts of the kingdom, so that learning and religion "might flourish more in her own sex." The distracted times of the great Civil War made it impracticable to carry out the plan, but Lady Falkland deserves a high place as the pioneer of projects for the higher education of women in the first half of the seventeenth century. F. W.

**FALSE POSITION.**—A rule that was formerly considered of great importance in the teaching of arithmetic. It is very ancient, having been known to the Egyptians, the Hindus, the Arabs, and the medieval Christians. In the Middle Ages it commonly went by such names as *Regula Falsi*, *Regula Falsi Positionis*, *Regula Positionis*, etc., and later as *La Règle de Faux*, *Regula Positionum aut Augmenti et Decrementi*. The use of the rule may be seen in the following example from Adam Riese (*q.v.*): "'God greet you 30 children.' Thereupon one of them answers, 'If we were as many again and half as many we would be 30.'" The solution consists in guessing a number (generally a false placing or position, whence the name), as 16. Then, by the conditions,

$$16 + 16 + 8 = 40, \text{ or } 10 \text{ too much.}$$

Try 14; then  $14 + 14 + 7 = 35$ , or 5 too much. Then write

$$14 \times 10 = 140$$

$$16 \times 5 = 80$$

$$\hline 60$$

$$\text{and } \frac{60}{10 - 5} = 12, \text{ the answer.}$$

In general, if we have to solve the problem

$$ax = b,$$

first let  $x = m$ ,

and suppose  $am = b - e_1$ ,  $e_1$  being the first error.

Let  $x = n$ ,

and  $an = b - e_2$ ,  $e_2$  being the second error.

$$\text{Then } a(x - m) = e_1,$$

$$\text{and } a(x - n) = e_2,$$

$$\text{whence } x = \frac{e_1n - e_2m}{e_2 - e_1}, \text{ which is the rule.}$$

The invention of algebraic symbolism rendered such circumlocution unnecessary, and so the rule passed away during the nineteenth century. It was merely a rule for attaining what algebra gives much more easily. There was a distinction made between the rule of single false position and the rule of double false position. The Arabs called the rule by a name which Leonardo of Pisa (see FIBONACCI) gave as *elchataym*. It therefore appears by such names as *El chataym* (Paciolo, *q.v.*), *per il Cattaino* (Cataneo, 1546), *Regole del Cattaino* (Pagani, 1591), and *Regola Hechataym* (Tartaglia, *q.v.*).

**FAMILY EDUCATION.**—The term "education" has so long been associated with "school" that there is a tendency to forget that the school is but one among many educational agencies, that one whose chief function is formal instruction. (See EDUCATION.) Of all educational institutions the most fundamental is the family. As Rosenkranz says, "The family is the organic starting point of all education." For the first six years of a child's life the family is normally the only educational institution. The family is the undifferentiated whole in which the child receives its first introduction to the social ideas of the larger world—economic, political, and religious. While family education may be regarded as preparatory to the school, it also performs an important function alongside the school. The relations among the members of a family are immediate, direct, and living. It is here that the child first learns the spirit of coöperation and acquires those virtues which lie at the root of social organization—sympathy, affection, gratitude, respect, obedience, and negation of the self. It must be recognized, however, that changing economic conditions have weakened family influences, and the tendency has been not to foster education in the home so much as to throw the burden on the teacher and the school.

In primitive society the child is early initiated into the struggle for existence, first through imitation of the occupations of his elders, and then by direct participation. Under the care of the father and the grandfather the boy learns to shoot, hunt, and fish; while under the care of the mother and grandmother the girl is taught the elements of household economy, industrial art, and agriculture. Under the same guidance follows adjustment to all the customs of the tribe and to the ceremonies due to the world of spirits. (See PRIMITIVE SOCIETY, EDUCATION IN.) In the early period of Hebrew and Roman history and among the Chinese (*qq.v.*) the family type of education is dominant. The primary aims are the inculcation of filial piety, loyalty to the members of the family living and dead, and self-control,—the subordination of the individual to the interests of the group. The Greek sub-

ordination of family to civic life finds its extreme statement in Plato's theory of the communistic nurture of children.

The modern conception of state control in education is the outgrowth of the Reformation, and is the result of reaction against ecclesiastical domination and of the recognition of the responsibility of the State with respect to the education of its citizens. Just as all our modern industries have been derived by a process of differentiation and specialization from the organized occupations carried on in the family, so likewise are the modern schools the product of specialization. First the Church and then the State assumed control of education. The first stage of state interference was to hold parents and masters responsible for the education of their children and apprentices, and this was done by compulsory examination and supervision. The best examples of this process are the Massachusetts law of 1642 and the Connecticut Code of 1650. (See COLONIAL PERIOD IN AMERICAN EDUCATION.)

But with the development of social consciousness, and the economic pressure which on the one hand led to congested city life and on the other tended to remove both parents from the home for the greater part of the day, the State stepped in and supplemented the efforts of the family. Compulsory school attendance (*q.v.*), free schools, kindergartens (*q.v.*), day nurseries or crèches, the feeding of school children (*q.v.*), and medical inspection (*q.v.*) are measures of state interference which not only benefit the State, but improve the possibility of healthy family life. It is objected that such measures free the family from responsibilities for which it naturally stands. To this it may be replied not only that the needs of society and humanity are above those of the family, but that such measures are educational and transitional. The same may be said of the introduction of school and district nurses, of visiting teachers, and of parents' or mothers' meetings. The vocational preparation of children has long been abandoned by the family, owing to the complexities of modern economic organization; but in this field the State can improve conditions of life by undertaking such training. Direct preparation for the duties of parenthood and family life is seen in the introduction of such subjects as care of infants, cooking, and the whole round of household arts. And though the extension of school activities may in many cases afford parents the opportunity to shirk their natural duties, yet the limitation of the school would not necessarily result in the strengthening of the educational influence of the family. To increase the efficiency of education through the family it is of prime necessity to secure improved conditions in the home and to supplement its deficiencies. Toward this end the economic and educational movements of the most progressive countries are at present directed in the following forms:—

1. Improved conditions for the home are provided by the various measures to relieve the congestion in the city by the erection of municipal and model dwellings, by cheap transportation, and by the various means taken to render more attractive the life of suburban and country communities.

2. The health and welfare of the child is essential to complete family life. If the wages of the young child are needed for the home, or if the parents are unable to provide for the necessary medical attention, and the family life consists in mere struggle for existence, progress becomes impossible, and it becomes necessary for the State to aid the parent in prolonging the period of infancy, which has been shown to be so essential in the formation of higher civilization. As communities realize the need of such aid, they undertake the feeding of school children, medical inspection, school clinics, special schools and classes for the defective children, etc.

3. Measures must be taken for the preservation of the family. In order that there may be family life, the wages of the adult members must be sufficient to support the family group. There must be leisure for the social life of the home, and wage earners, especially the mother, must be protected from hazardous and degrading employment. The period of productiveness must be extended; care of the aged must not exhaust the resources which are necessary for the young; finally, the family group must be preserved, even when deprived of the chief wage earner. As a means, therefore, toward the conservation of the home the following measures are now generally demanded: (a) limitation of the hours of labor; (b) restriction in the employment of young children (see CHILD LABOR; CHILDHOOD, LEGISLATION FOR THE CONSERVATION AND PROTECTION OF); (c) liability of employer in case of accident; (d) compulsory insurance; (e) old age pensions; (f) special aid to widows with children.

**Inadequacy of the School as an Educational Agency.**—The school is inadequate for the following reasons. (1) It occupies less than one-eighth of the child's time during only a limited period of life. It is not sufficient to overcome neglect of the home or the evil influence of the street. It is too brief a time for the establishment of good habits of thought, speech, and behavior. (2) The school lacks continuity of social influence. The child is passed along from group to group once a year, and often at shorter intervals, with frequent changes of teachers, and has but little opportunity to develop a feeling of social solidarity or responsibility. The entire plan of the school is artificial from the standpoint of social organization. All attempts at overcoming these disadvantages, in the various plans of school cities and other forms of self-government, have thus far only tended to further accentuate this artificiality. (3) As the school is organized for the purpose

of the instruction of pupils of similar attainments, group conformity is the chief virtue; while in the home we have a group of people of different ages and attainments working in co-operation, each fulfilling a different function. Here is afforded opportunity for self-reliance and individuality. (4) The school is subjective rather than objective, egoistic rather than altruistic; even in the case of various forms of manual training, whatever is produced is for the sake of instructing the child and does not usually represent the child's contribution for the interest of others.

**The Child in the Home.**—The emperor, Marcus Aurelius, thanked the gods that he had the satisfaction of his mother's life and company a considerable while, though she was destined to die young. The care and early training of the infant is the special province of the mother as nurse and guide, whatever theory may be held as to the relation of the home and the school in the education of the child. Comenius, to whom we owe the modern system of school grading, called the first six years the mother's school, and found in this the elements of all later education, — intellectual, moral, and religious; even the rudiments of natural science and philosophy. According to Rousseau, as the real nurse is the mother, the real preceptor is the father; and in order to justify the employment of a tutor to fulfill the duty which naturally belonged to the father, Rousseau found it necessary to imagine Émile an orphan. Pestalozzi began his educational career by taking into his own home a number of neglected children and treating them as members of his own family. According to his idea of education as pictured in *Leonard and Gertrude*, the true teacher is the mother who keeps her children occupied in household duties, and at the same time instructs them in the arts of reading, writing, and arithmetic. Pestalozzi's principle was that it is life which educates; and that the moral, intellectual, and industrial center of elementary education must be found in the sympathy, ideas, speech, and intelligent activities of a well-organized family life. Froebel completed the thought of Pestalozzi. He taught that only in the family is real experience to be found; only as a member of the family will it be possible for man to become a symmetrical, real, whole man; only in the family is there complete provision for the fundamental need of childhood, — self-expression (*Education of Man*, pages 101–102). The primary purpose of early home training should be the establishment of good habits and the practice of obedience. The young child should be permitted peace and quiet; many of his faults should be ignored; the standards and opinions of elders should not be enforced upon him, but his own personality should be preserved. The child must, however, adjust himself to the habits of the household and feel his responsibility as a member of the family circle. The child should not expect to

be entertained, but should be given simple toys which afford opportunity for initiative. Love of nature should be cultivated by calling attention to flowers, trees, birds, etc., during walks. Through story telling and reading aloud an interest in literature may be aroused and the desire to read stimulated.

The moral and social influences of the home present the following characteristics: "Service from sympathy, service without a sense of patronage or humiliation, and service as the expression of each emotion," which, "together constitute the ideal which should inspire the relations of the man to his fellow-creatures" (Bray, *The Town Child*).

**Home and School.**—When school age is reached, the duty of the parent with respect to education cannot be fulfilled by sending the child to school. "Those parents," says Plutarch, "are to be blamed who, when they have committed their sons to the care of pedagogues or schoolmasters, never see or hear them perform their tasks; wherein they fail much of their duty. For they ought, ever and anon, after the intermission of some days, to make trial of their children's proficiency; and not entrust their hopes of them to the discretion of a hireling. For even that sort of men will take more care of the children, when they know that they are regularly to be called to account. And here the saying of the king's groom is very applicable, 'that nothing made the horse so fat as the king's eye.'" There must be unity of aim and co-operation in method on the part of the most important educational institutions, home and school. To further this co-operation, visits of parents to the school and of teachers to the homes are becoming general. In New York the experiment is being tried of employing additional visiting teachers whose sole duty is to secure a helpful relation between the home and the school. Parents' associations are frequently the outgrowth of mothers' meetings, an established feature of the kindergarten. Through such meetings and associations parents receive suggestions as to home care of children and keep in touch with school aims and methods. The Parents' National Educational Union (*q.v.*) of England has for its aim the enlightenment of parents with respect to instruction and training at home or in private schools. Definite courses of study are prepared under the auspices of the Union.

True co-operation of the home and school, however, cannot be brought about by the subordination of the home; by making the home, as is so often the case, merely a preparation for school. Instead of hearing spelling lessons, parents should read with their children the great classics which appeal alike to young and old. Instead of having school tasks to upset the home, the home should possess its own duties and pleasures. "What is required above all," says Ellen Key, "for the children of the present day, is to be assigned again real home

occupations, tasks they must do conscientiously, habits of work arranged for week days and holidays without oversight, in every case where the child can help himself." "The strongest constructive factor in the education of a human being is the settled, quiet order of home, its peace, and its duty. . . . The house once more becomes a home for the souls of children, not for their bodies alone. For such homes to be formed, that in their turn will mold children, the children must be given back the home. Instead of the study preparation at home for the school taking up, as it now does, the best part of a child's life, the school must get the smaller part, the home the larger part. The home will have the responsibility of so using the free time, as well on ordinary days as on holidays, that the children will really become a part of the home both in their work and in their pleasures. The children will be taken from the school, the street, the factory, and restored to the home. The mother will be given back from work outside, or from social life, to the children. Thus natural training in the spirit of Rousseau and Spencer will be realized: a training for life, by life at home."

**The Social Significance of Family Education.**—Not wholly without reason, it has become customary to regard the school as the most important means of controlling the future. Specific instruction in the schools is demanded, that temperance, thrift, chastity, and civic duty may form the ideals and the practice of the rising generation. Too much is expected of the school alone. According to Professor Giddings, "There is no radical cure for degeneration but in a pure and sane family life, which disciplines the welcome and untainted child in the robust virtue of self-control, and in an unswerving allegiance to duty." J. F. R.

**FANCY.** — A term employed to designate those forms of mental activity in which the individual builds up combinations of experience without serious reference to the correspondence between these forms of experience and any objective reality. Thus one may build up in his fancy the notions of animals or buildings which could not be realized in any external experience. Fancy is one phase of imagination (*q.v.*).

C. H. J.

**FARADAY, MICHAEL** (1791-1867). — Famous English scientist, born of humble parentage at Newington Butts, Surrey. After a brief education in the elementary subjects, he became in 1804 errand boy, then apprentice, to a stationer and bookbinder. He took an interest in books, particularly those bearing on scientific topics. In his spare hours he dabbled in chemistry and electricity. In 1812 an opportunity offered of attending some lectures by Sir Humphry Davy, the notes of which Faraday carefully copied out and bound. In 1813, becoming tired of business pursuits, he offered his services to Davy, who obtained for him the position of laboratory assistant in the Royal Institution. After a period of nearly two years spent in travel with Sir Humphry, during which he came into contact with the most prominent scientists of the day, he renewed his work at the Royal Institution, with which he remained intimately connected until his death. Stimulated by an ambition to become a lecturer, he began to take a prominent part in the proceedings of the City Philosophical Club, consisting of young enthusiasts like himself, took lessons in elocution, and studied the methods of the prominent scientists who lectured at the Institution. Until 1821 he assisted Davy in his researches, but about that period he began to make original researches on his own account. Beginning with his discovery of electromagnetic rotations in 1821, he was able in 1831 to perfect his work on magneto-electricity and induction, which laid the basis for future improvements in the applications of electricity. His researches were also conducted in chemistry, and in this field he discovered new compounds which later made possible the use of aniline dyes. His published works, including articles and reports, are *Experimental Researches in Electricity* (1839-1855), and *Researches in Chemistry and Physics* (1859). As early as 1823 he was elected a Fellow of the Royal Society, and he became a contributor to the chief scientific reviews. From 1823 to 1862 Faraday lectured regularly at the Royal Institution, with the exception of the four years 1840-1844, when through ill health he was compelled to cease work; but even in this period he did not discontinue his Christmas lectures to juveniles, which commenced in 1827 and always continued to give him pleasure. Offers

of promotion and advancement were persistently refused in order to be able to give more time to researches. Because it did not make much demand on his time, he consented to lecture at Woolwich Academy (1829-1849). In 1836 he became adviser to Trinity House, which has charge of lighthouses. He was without a rival as a lecturer, not only because he was deeply inspired with the meaning of his subject, but also because he studied himself with the purpose of acquiring perfection on the platform. And as an experimenter he stands in the forefront of scientists. Honors continued to be showered upon him, but of all he valued most his fellowship in the Royal Society and his place on the Senate of the University of London. In the last position he was able to make some recommendations on examinations for scientific degrees, holding that neither a written nor an oral test was adequate; and at Woolwich he gave instructions that the students' notebooks should be examined.

In his opinions on education Faraday did not rise above the prevailing disciplinary views, except that he ranged himself on the side of sciences as against the classics, although in a remarkable lecture on the *Education of the Judgment*, delivered in 1854 in the presence of the Prince Consort, he began with the statement that "Education includes all that belongs to the improvement of the mind." The theme of this essay was the deficiency of judgment in the exercise of the mental powers. Men, he says, are willing to rely on the senses alone, without further examination, while the best basis for judgment includes not only carefully observed facts, but the laws of nature. Hence education must be of the self; self-examination, self-criticism, sincerity, recognition of ignorance, and readiness to accept correction, — these are the marks of true education and mental discipline. There is in us too strong a tendency to discover what we wish to discover. Clear and precise ideas, and clear and definite language are necessary if the sense and love of truth are to be attained. Comparison, balance of data, proportionate judgment, suspense of judgment are all steps in the process of reaching truth. Book-learning Faraday distinguished from the exercise of judgment which can be improved and trained in any field by mental labor. In urging the cultivation of the scientific spirit Faraday makes constant reference to the unscientific acceptance by his own contemporaries of table-tipping and other devices of spiritualism. The lecture, however, is one that can be read in any generation.

Faraday was one of the witnesses examined by the Public Schools Commission in 1862. He deprecated the claims made by the supporters of classics and pure mathematics for the mental discipline imparted by these subjects, citing examples within his own experience of men highly educated in the accepted sense of the term who had acquired such habits

of mind that in relation to natural phenomena they had to begin at the same point as children, and must learn the A B C of things. The old training was also the cause of a supercilious attitude toward the new knowledge as nonsense. While not attacking classics, he insisted at any rate that they were not the whole of knowledge, and so far as the transfer of powers through a classical training is concerned, he says, "Society at large is almost ignorant of the like and greater value of the kind of study which I recommend." While Faraday's influence on education was not positive, he belonged to that group of scientists of the middle of the nineteenth century who indirectly affected the schools through the social recognition which they won by their eminence in the new field.

**FARGO COLLEGE, FARGO, N.D.**—A coeducational institution, founded in 1887 by the Congregational churches of North Dakota, but now undenominational. Preparatory, collegiate, and music and art departments are maintained. Candidates are admitted on certificates from high schools and on examination, the requirements for which are equivalent to fifteen units of preparatory work. There is a faculty of thirty members.

**FARNABY, THOMAS (1575-1647).**—Possibly the greatest English private schoolmaster of the seventeenth century. Anthony à Wood describes him as the chief grammarian, rhetorician (Latin), poet, Latinist, and Grecian of his time. Born the son of a London carpenter about 1575, Farnaby in 1590 entered Merton College, Oxford, where he was postmaster to Mr. Thomas French. He left the college abruptly. After a roving life as sailor and soldier, he returned to England and settled at Martock, Somersetshire, where he "stooped so low as to be an abedarian, and several were taught their hornbooks by him, and in the neighborhood of Martock were found in later years those who had been his old pupils, who had become good grammarians." Farnaby, on leaving Martock, opened a school in Goldsmiths' Rents in Cripplegate, London, and is reported to have worked up his private school there to the number of "three hundred or more, including many young noblemen and other generous youth." He is said to have had separate rooms for the different forms,

and three ushers, one of whom was young Alexander Gill (*q.v.*), whose father was the head of St. Paul's School. Another usher was William Burton, the antiquary. An interesting account of Farnaby's method of dealing with a pupil is seen in the "Autobiography of Sir John Branston" (*Camden Society Reprints*, page 101). Farnaby removed his school, in 1636, to Sevenoaks in Kent. He became rich, and was probably the first English schoolmaster who made a fortune. In the great Civil War he took the king's side, and was arrested by the Parliamentarians at Tonbridge in 1643, and imprisoned at Newgate. In 1645 he was allowed to return to Sevenoaks, where he died in 1647.

Farnaby edited the following classics: *Juvenalis et Persii Saturae*, 1612; *Senecae Tragoediae*, 1613; *Lucani Pharsalia*, 1618; *Martialis Epigrammata*, 1615; *Vergilii Opera*, 1634; *Ovidi Metamorphoses*, 1637; *Terentii Comediae*, 1651. Many of these went through numerous editions, and were well known on the Continent. In addition, Farnaby also issued several school-books, including the following: *Phrases oratoriae elegantiores et poeticae*, London, 1628, 8th edition mentioned by Wood; *Index Rhetoricus, scholis et institutioni tenrioris aetatis accommodatus, cui adjiciuntur Formulae Oratoriae*, 1633; *Systema Grammaticum*, 1641; this grammar was written by royal order and was specially authorized; *Florilegium epigrammatum Graecorum, eorumque Latino versu a variis redditorum*; 1629; this *Florilegium* of Greek epigrams is of course the Greek anthology collected by Maximus Planudes. Farnaby collected the translations of the Greek into Latin verse by Sir Thomas More, H. Stephens, Erasmus, Lily, Aleiat, Scaliger, Buchanan, etc., and supplied some himself. Of these books, the *Index Rhetoricus* ran through the greatest number of editions. The earlier parts of Farnaby's *Index Rhetoricus* are occupied with an account of rhetorical treatment of matter and form in any composition, oral or verbal. In this system, great stress is laid on oratory, for a composition should be elegant, and it should be dignified; and, above all, the composition must be *apt.* F. W.

**FARNHAM, GEORGE LOOMIS (1824-1900).**—Advocate of the sentence method in teaching reading; was educated in the common schools of New York and at the Albany Normal School under David P. Page (*q.v.*). He was principal and superintendent of schools at Syracuse; superintendent of schools at Binghamton, N.Y., and Council Bluffs, Iowa. From 1884 to 1893 he was principal of the Nebraska Normal School at Peru. Author of *The Sentence Method of Teaching Read-*

ing (Syracuse, 1887), and of several papers and addresses on the same subject. W. S. M.  
See READING, METHODS OF TEACHING.

**FARRAR, FREDERICK WILLIAM** (1831-1903). — English schoolmaster, author and clergyman; born in Bombay in 1831. He graduated at Trinity College, Cambridge, where in 1856 he was elected to a fellowship. He entered holy orders and received an appointment as assistant master at Harrow. In 1871 he became Headmaster of Marlborough College, where he was successful in raising the school from the decline into which it had temporarily fallen. In 1876 he became Canon of Westminster, and in 1890 Dean of Canterbury. Farrar was a prolific writer on theology, education, and history, and was the author of some stories which for many years enjoyed a remarkable vogue. Among these are the school tales, *Eric, or Little by Little; A Tale of Roslyn School; St. Winifred's, or the World of School;* and *Julian Home*, all to some extent autobiographical. A book of a different kind and perhaps even more widely read was his *Life of Christ*. Dean Farrar played a very important part in the movement of the reform of the curriculum, and in introducing generally the so-called modern subjects. In 1867 and 1868 he lectured at the Royal Institution on *Public School Reform*, when he attacked the traditional classical education and pleaded for the broadening of the curriculum. To the *Essays on a Liberal Education* (London, 1867), which he edited, he contributed an article on *Greek and Latin Verse Composition as a general Branch of Education*; a plea for a much broader course of studies than the classical. Another contribution to education was the lecture on *General Aims of the Teacher*, delivered at Cambridge in 1883, containing advice and suggestions to teachers culled from his own experience. While Farrar did not possess the administrative ability to carry his suggested reforms into effect, there is no doubt but that the weight of his influence contributed greatly to the changes which came into the English schools in the last quarter of the nineteenth century.

**FATHERS OF THE CHURCH**. — See CHRISTIAN EDUCATION IN THE EARLY CHURCH; and the special articles on the various fathers.

**FATIGUE**. — A condition of the organism characterized objectively by a reduction of efficiency, and subjectively by a complex of feeling and sensation (particularly the feeling of weariness and sensations of strain and fatigue, mainly peripheral in origin), by a disinclination to exert effort, and ultimately by a desire to sleep. We speak of physical or of mental fatigue, according as the functional inefficiency appears in physical or in mental work, and we speak of fatigue by bodily activity or of fatigue by mental activity, according as the activity that induced the functional inefficiency was physical or mental. Both in investigating fatigue experimentally and in applying the results of investigation in practice, we must distinguish between these subjective and these objective aspects, since we find that there is no thoroughgoing uniformity in their interrelations: in particular, many individuals can do work that is objectively satisfactory, when they experience all the subjective symptoms of fatigue. To what extent we are warranted in encouraging children to exert effort under these circumstances is another matter. In general, the subjective symptoms may be regarded as protective devices, as warnings that work should give way to rest. Exhaustion is an extreme form of fatigue, in which functioning is, as a rule, not only inefficient, but also disordered — in which, then, fatigue has passed into a pathological condition. Overburdening or overloading are terms applied, in educational parlance, to a condition in which the demands made upon the pupil are excessive, with the result that the ordinary processes of sleep and nutrition do not suffice to remove the fatigue from day to day, and that the fatigue effects are cumulative, and lead ultimately to neurasthenia, general debility, or some other form of general breakdown.

The older theories of fatigue, of which Verworn's is typical, envisaged the condition with relative simplicity in chemical terms. Negatively, fatigue represents a consumption of materials, especially of oxygen, carbon, and sodium; positively, it represents a production and accumulation of waste products of metabolism, especially of lactic acid and acid potassium phosphate, the "fatigue substances" or "fatigue poisons." Weichardt has recently claimed the discovery of special antitoxins formed within the organism in reaction to the fatigue toxins. Injection of these antitoxins affords temporary immunity to fatigue, in the case at least of the small animals experimented upon.

While this chemico-physiological theory may be adequate to explain simple examples of fatigue, e.g. in the stock nerve-muscle experiment of the physiologist, it is inadequate (despite Lee's ingenious extension of the Treppe theory to mental work) to the vastly more complex conditions that govern mental fatigue in the human organism. Recent

theories of fatigue (*c.g.* Yoakum, MacDougall) show a tendency to follow Sherrington and other physiologists in envisaging neuromuscular activity in terms of the "reflex-arc concept," and to utilize especially the idea of the "resistance" or "blocking" of nerve paths at the synapses of the neurones. These are, as yet, however, but speculative hypotheses. The course of mental efficiency, as is shown below, is complicated by numerous psychological factors, the reduction of which to physiological terms is certainly difficult, and perhaps of little practical advantage.

Another important theoretical problem concerns the question whether fatigue is general or specific (local). It is important, because, if fatigue set up in a specific structure is rapidly disseminated through the organism by the circulation of the blood, we may hope to measure fatigue indirectly; we may hope, for instance, to measure the fatigue of a school hour by its effect on muscular endurance as revealed by the ergograph. Again, if fatigue is essentially specific, then change of work would be an important device for ensuring maximal net efficiency. The truth appears to be that fatigue is both specific and general: when it first appears, and when it is mild, it is, in the main, localized in the active structures; but there is no strict isolation of the fatigue effects, both because the active structures disseminate their waste products through the entire organism, and probably, too, draw upon other structures for a supply of energy, and also because our psychophysical activity is not really as specific as it seems. In effortful thinking, for example, muscles in various parts of the body are under strain; we may feel tired in the back of the neck from the solving of problems in mental arithmetic.

**Measurement of Fatigue.** — In theory, this may be directed either to the subjective or to the objective aspects. As already noted, the former are too unreliable to serve as indexes of the reduction in efficiency, besides being intrinsically difficult of measurement. The objective aspects may be measured either by physiological or by psychological methods.

1. In tests of school children, the *physiological method* has included the use of the dynamometer (chiefly for measuring strength of grip) and of the ergograph (*q.v.*) (for measuring physical endurance, *e.g.* in voluntary contraction of the finger), the recording of pulse and respiration, of the speed of voluntary movement (tapping test, as in the work of Wells), and of the range of accommodation of the eye (Baur). Pulse and respiration prove to be too much subject to fluctuation from other causes; tapping and accommodation, while of much theoretical interest, have not yet been sufficiently tried out to warrant generalization; the ergograph has, however, been the object of extensive critical investigation, the net result of which is to show that,

while the instrument may be adapted for measuring general physical efficiency (for certain individuals and under exact experimental control), there is no definite and reliable correspondence between the ergographic record and the mental efficiency of the pupil that would warrant the general use of the method for measuring fatigue in the school.

2. The *psychological method* embraces two main types of procedure, the method of discrete tests and the method of continuous work. The principal mental tests that have been applied to the measurement of mental fatigue are copying (Schuyten), dictation (Sikorski, Friedrich), computation (Burgerstein, Laser, *et al.*), rote memory (Ebbinghaus, Netschajeff, Schuyten), cancellation (Bourdon, Ritter, Binet), the Ebbinghaus completion test, the combination method of Teljatnik, the pattern tapping test of Squire and Yoakum, together with the estimation of time intervals (Lobsien) and the determination of various liminal values, *e.g.* sensitivity to pain (Vannod, Swift, Claparède), and the discrimination of two tactual stimuli. Of these tests, the last-named, commonly known as the compass-point or *æsthesiometric* test, or as the Griesbach method (see *ÆSTHESIOMETER*), has called forth the most discussion. The value of the method has been upheld by Blazek, Keller, Vannod, Wagner, Heller, Bonoff, Ferrari, Sakaki, Schuyten, Joteyko, Abelson, and others; it has been assailed by T. L. Bolton, Kraepelin, Leuba, Germann, Ritter, Gineff, and Meumann. All in all, though subject to obvious defects, some of which may be remedied and others not, these psychological methods, as applied in discrete tests, have yielded useful average values and have afforded valuable information as to the effect and degree of fatigue. Their chief defect lies in the fact that when applied as bits of test work, inserted into the course of other fatiguing work, they do not permit us to follow the development of fatigue step by step.

3. In the *method of continuous work*, as exploited particularly by Kraepelin and his pupils, and as applied generally in laboratory experimentation, the test work itself constitutes the fatiguing work, and is, therefore, continued uninterruptedly for relatively long periods, say for an hour or for several hours. Examples of this method are the computation tests of Burgerstein, Holmes, Thorndike, Kraepelin, *et al.*, the test with Latin verbs of Merian-Genast, the dictation tests of Höpfner. One of the chief contributions of this method is the demonstration that the course of mental efficiency in long-continued work is conditioned, not only by fatigue, but also by several other factors, notably by practice, habituation, "warming-up," "swing," or fitness for work, and by various types of "spurt," — possibly also by yet other independent fluctuations of psychophysical efficiency. To measure fatigue,

therefore, we must disentangle it from these concomitant factors.

**Results.**—The net outcome of these experimental investigations is the establishment of a number of fairly well-defined laws of fatigue. Much remains to be done, but we know that individuals fall into four fairly distinct types of fatigability; that fatigability is a function of age; that sixty minutes is too long a lesson period for the average school child; that the forenoon are more favorable than the afternoon hours; that formal school work should not exceed five hours per day or twenty-five hours per week; that home work should be reduced to the minimum and arranged so that it will not exact intensive application; that short pauses, when filled with free play out of doors, but not with gymnastics, are invaluable offsets of fatigue; that the pauses should increase in frequency and in length as the work continues; that a pause, even of short duration, may work disadvantageously when it interrupts easy work of relatively long duration; that the noon intermission often fails to fulfill its desired recuperative effect because afternoon work begins before digestion is sufficiently advanced; that pupils should obtain from nine to eleven hours of sound sleep;—a desideratum all too frequently unfulfilled—that adequate sleep is the best protection against overburdening; that a change of work does not add positively to the store of energy, but may operate advantageously by setting aside ennui; that exercise, especially in the form of free play, consumes energy, yet is of benefit because it stimulates metabolism and accelerates the removal of waste products; that gymnastics constitute a positive source of fatigue for many pupils; that the fatigability of school work is partly a function of the subject, partly of the method of instruction, and partly of the teacher; that individual instruction is more fatiguing than class instruction; that the school program should be planned to bring the hard subjects early, to alternate hard and easy work, and to insert frequent and progressively longer pauses.

**Questions of practical interest.**—Two important questions arise: Is our present school work calculated to produce overburdening? Is it permissible that pupils should work after they show signs of fatigue? For the first query, the evidence appears conclusive that in this country, however it may be in Germany, where the topic has been most under discussion, the regular work of the school does not lead to overburdening in the case of the average healthy pupil. As for the second query, nearly all authorities agree that, while we must not permit fatigue to be carried to exhaustion, with consequent slow or perhaps permanently incomplete recovery, we need not worry because children show signs of weariness, provided the conditions are hygienic as regards air supply, temperature, humidity, methods of work, and

the like. Teachers must learn to distinguish between pseudo-fatigue and real fatigue. They must remember that a cardinal element in mental training is the development of a capacity in some measure to disregard the feeling of weariness and to stand up under the pressure of fatigue. But the preaching of this gospel of work carries with it the obligation to teach children how to economize their time and strength, how to study efficiently, how to work to best advantage. The practical problem of fatigue is, in other words, how best to utilize and to conserve human energy. G. M. W.

**FAWCETT, HENRY** (1833-1884). — English statesman and economist, born at Salisbury. One of the schools which he attended was Queenwood College, an agricultural school established by Mr. George Edmondson somewhat on the lines of Fellenberg's school at Hofwyl. Here Fawcett may have acquired that lifelong interest which he showed in agricultural questions. After attending King's College School in London he proceeded to Cambridge, graduating in the mathematical tripos in 1856, and obtaining a fellowship at Trinity Hall. An accident deprived him of his sight, and diverted him from a career at the bar. He turned his attention to economics, contributed papers to the British Association (1859), and wrote a *Manual of Political Economy* (1863). He was a friend and disciple of John Stuart Mill (*q.v.*). In 1863 he was appointed Professor of Political Economy at Cambridge, and held the position till his death. About this time he devoted himself to politics and entered Parliament in 1865, and with a brief interval remained a member of the House of Commons until his death, rising to the position of Postmaster-General, an office in which he showed great efficiency. He was prominent in Parliament in all questions affecting social welfare and education, and himself declared in a speech, "I started political life caring more about the general education of the people than about any other question that is likely to be discussed in this House." While a member of the Cambridge Union he had opened debates on national education and university reform. He was a strong supporter of the movement to abolish tests for degrees and fellowships at the universities of Oxford, Cambridge, and Dublin. The official government measures for University Reform (1871) he opposed on the grounds that the clerical fellowships and tests in college statutes were not removed. In the universities he desired to see the culmination of a national system of education. He criticized keenly the Education Act of 1870 because the establishment of compulsory education was not made mandatory on local authorities, and he kept up his opposition to "permissive compulsion" until 1880, when compulsory education became imperative. To the agitation for free schools he was opposed on the grounds that, while in establishing compulsory education the State acted as the protector of the young, there was no more reason for making education gratuitous than for the State to provide food and clothing to children. Free schools would reduce the interest of parents in education, and would pauperize; all parents should make a sacrifice for the education of their children, or else receive poor relief and so be stigmatized as paupers. In any case he argued free education merely shifted the burdens, and school support would be indirect. On the question of religious education Fawcett would have preferred to

see a system of secular education, and one of the reasons for his breach with the Birmingham League was that it was stirring up "a miserable sectarian squabble." Fawcett was also the spokesman for an extension of the educational provisions to agricultural laborers, whose helplessness was largely due to ignorance. Irish university reform claimed a large share of his attention, as well as the growing demand for the higher education of women, a movement in which his wife, Millicent Garret Fawcett, took a prominent part. Fawcett claimed equal opportunities for the education of women, because he was opposed to restrictions of all kinds, and supported the proposal that women should be admitted to the Cambridge local examinations.

**FEAR.** — An instinctive recoil from objects that are strange or large or in rapid motion toward one. It is a type of negative reaction. It is protective in its character, and common to all animal forms. C. H. J.

See EMOTIONS; INSTINCT.

**FECHNER, GUSTAV THEODOR** (1801-1887). — Student of medicine, physicist, philosopher, and founder of psychophysics and quantitative experimental psychology. He embodied a "happy combination of observation and philosophical speculation." He was professor of physics, and later professor of philosophy, in the University of Leipzig. During a period of forty years he made valuable contributions in various fields. He wrote about seventy-five books and articles in the field of physics, mathematics, electricity, physical optics, religion, evolution, æsthetics, ethics, metaphysics, psychology, and psychophysics. He believed in a universal animism; plants, animals, and celestial bodies alike possess souls. He applied the principle of the conservation of energy to the physiological phenomena accompanying consciousness, and gave fifty of his best years to the investigation of the exact relation between the mental and the physical — between the intensity of sensation and the intensity of the stimulus. These researches — notable examples of caution, patience, and erudition — appear in his epoch-making work, *Elemente der Psychophysik*. In this work he collected many scattered observations from physics, astronomy, and biology; gave the results of his own elaborate investigations in the field of tactual, visual, and auditory sensations; offered sundry philosophical generalizations; and formulated the first great uniformity experimentally es-

A GROUP OF GERMAN EDUCATORS AND PHILOSOPHERS.

established in psychology, the so-called Weber, or Weber-Fechner law. This law — that the intensity of the sensation varies as the logarithm of the stimulus — assumed in psychology the importance ascribed to the law of gravity in physics, and raised psychology to the dignity of a science.

Fechner was a man of most varied attainments, but his fame rests chiefly on his psychophysical researches. His psychophysical law, whatever its value, inspired numerous attempts at verification, further investigations, and a sea of critical articles. These works produced a healthy reflex influence upon the development of scientific psychology. If Fechner had not lifted a couple of weights to determine the differential limen, experimental psychology would be quite different from the science as we know it to-day. While Fechner's relation to education is indirect, it is none the less important. Without Fechner there would have been no psychophysics, or at least its development would have been much retarded; without Fechner's psychophysics there would have been no exact quantitative psychology, or its appearance would have been delayed; and without modern experimental psychology the scientific study of educational problems would still follow the crude methods of a generation ago.

The chief writings of Fechner are *Elemente der Psychophysik* (1860), *Zur experimentalen Aesthetik* (1871), *Vorschule der Aesthetik* (1876), *In Sachen der Psychophysik* (1877), *Revision der Hauptpunkte der Psychophysik* (1882), *Über die Psychischen Massprincipien und das Webersche Gesetz* (Wundt's *Philos. Stud.*, IV, 1887, pp. 161-239). J. E. W. W.

See portrait opp. p. 582.

**FEELING.** — A popular term which has also been used in technical psychology to distinguish a phase of mental life, which is exemplified by such experiences as pleasure, displeasure, excitement, and strain. In popular parlance the word is very commonly used also to refer to skin sensations and organic sensations. In technical writing this use of the term is not favored, a distinction being drawn between sensations and states of pleasure, excitement, etc., which are regarded as distinct from sensations. Organic sensations are frequently accompanied by intense feelings of pleasure or displeasure, and consequently there is justification for the close relationship in ordinary usage between the term "feeling" and the organic sensations.

Feeling is one of three distinct types of mental activity long distinguished in psychological literature. (See **MENTAL PROCESSES, CLASSIFICATION OF.**) It is contrasted with intellect and volition. In its complex forms it manifests itself in emotions (*q.v.*). Various views exist with regard to the different types of feelings. Some writers distinguish only two varieties of feelings, namely, pleasure and displeasure. (Külpe, *Outlines of Psychology.*) Others distinguish six. Thus Wundt (*Outlines of Psychology*) distinguishes pleasure, displeasure, strain, relaxation, excitement, and depression. Feeling is intimately related to activity. C. H. J.

See **EMOTION.**

**FEES.** — So little has been written or is known of the history of school fees and charges that Dr. Kennedy's dictum in a famous paper (see **FREE SCHOOLS**) that all schools were free before the Reformation and that school-keeping was not "a gainful profession" has been accepted almost as a truism. It is in fact the reverse of the truth. The earliest school references in literature show that tuition-fees and entrance-fees were the rule, free education the exception. Thus the "Mean man" in Theophrastus' *Characters*, written c. 300 B.C., if his sons do not attend school every day because they are ill, makes a proportionate deduction from the fees and in the month of Anthesterion, in which there are many holy days, will not send them at all, so as to save the fees. In Greek Schools the fees were paid monthly at the end of the month and voluntary absence made no difference, as the angry mother of a truant son in the *Mimes* of Herondas c. 250 (iii. 3) complains that he hardly knows the school door by sight, but she has to pay on the 30th all the same. As to what the fees were, no indication is given. The elementary schoolmasters, like those of England before 1870, were a poor and despised class like Æschines' father who, when ruined, betook himself to teaching, with Æs-

chines to help him "in grinding the ink and sweeping out the schoolroom, the work of a slave not of a free boy," while Lucian in relegating tyrants in a future state to the position of elementary schoolmasters puts them on a level with the vendors of fried fish in the streets. The sophists, who may be compared with our university lecturers or the headmasters of great public schools are said by Plato, their great rival who charged no fees, to have made large sums. Thus Prodicos charged £2 for a single lecture, though it could be had in a short form for 10*d*.; while he also had lectures at £5, 1*s*. 5*d*. and 3*s*. 4*d*. (Plato, *Arioch*, 366, in Freeman's *Schools of Hellas*, p. 168). Isocrates however a few years later says that Gorgias, the most successful of his time, who never married or paid any taxes, only made about £800. A whole course in ethics was given for only 3 or 4 minas or £12 to £16.

The only evidence of the amount of tuition fees in Roman schools is a line in which Horace (*Sat.* I. 6, 7, 5) says that his father took him to school at Rome as he did not care to send him where his country neighbors sent their sons at 8 asses a month, which Dr. Wilkins (*Roman Education*) says is about 4*d*. a month, or 1*s* of our money. Even this is a disputed reading. Quintilian (*q.v.*), a century later, made a fortune, but in this respect, Juvenal calls him a white crow. When the Roman schools were endowed by the Emperor Vespasian he gave the rhetoric schoolmasters 10,000 sesterces, equal to £800 a year. Gratian, 300 years later, in 376, ordered that a rhetoric master should have 24 *annonae*, and a grammar master half that, equivalent to about £1248 and £624 a year, taking an *annona* or the year's pay of a working man at £1 a week. In Trier, the then capital of the Western Empire, the tariff was 30 *annonae* for rhetoric, 20 for Latin, and 12 for Greek grammar masters.

In England, the earliest mention of school fees yet forthcoming is at Bury about 1180, when Abbot Samson bought a stone house in the town and assigned it for a school, on condition that poor clerks should be forever free of the contribution to the master for rent of a penny or a halfpenny twice a year. Some eighteen years later he endowed the master with a pension of 3 marks (£2) a year from a rectory, and directed that in return, forty poor clerks should be quit of all pennies (*denariorum*) which the schoolmaster, according to custom, exacted for his teaching. Whether the tuition fee really was a penny, *i.e.* a penny a quarter, or 4*d*. a year, does not exactly appear. But that would amount to £1 3*s*. 4*d*. a year on forty boys, giving two thirds of the benefit of the endowment to the parents of scholars, among whom the monks' relations had a preference for being free scholars, and one third to the master.

It is not till a century later that we get a

record of the tuition fees actually paid, and this is at Oxford in the Merton College accounts of the founders' kin for whom the College had to provide a grammar school education. In 1277 the College paid the master of glomery (a corruption of grammar) for five boys 1*s*. 8*d*. from April 14 to July 20, *i.e.* one term, or at the rate of 4*d*. a head a term. Their washerwoman and serving boy together cost precisely the same, and one pair of stockings at 8*d*. cost twice as much as their teaching, while their commons or board was at the rate of 8*d*. a week. In 1300 the same sum of 4*d*. a head a term was paid for seven boys, with 2*d*. more for the vice-monitor's *dica* or tip, and 1*d*. to the boy, probably the boy who swept the school. In 1305 4½*d*. each was paid for eight boys for the winter term, 6*d*. for two other boys, while in the Lent term 5*d*. each was paid for seven boys, and in the summer term only 4*d*. In 1308 the "seolage" of nine boys with the usher's *dica* came to 4½*d*. each, of which probably the master got 4*d*. and the usher ½*d*. There were apparently only three terms a year, the autumn term being occupied by the long vacation. In 1347 Master John of Cornwall, who is celebrated as being the first grammar schoolmaster who taught the boys to translate Latin into English instead of French (see ANGLONORMAN DIALECT) was paid 10*l*. for the salary of his school, *i.e.* apparently rent for the schoolhouse with 2½*d*. to his usher, and 4½*d*. each a term was paid for tuition fees. Another 2*d*. a week was paid for having the grammar boys taught writing, whether to the same master or another, does not appear, but this was apparently in the long vacation. So closely were the fees calculated that, when one of the four boys learning writing was ill for half a week, the college, like the "Mean man" in Theophrastus, only paid a penny for him. A *donat*, or elementary grammar, cost, in 1309, 3*d*.; and a Horace in a feeble state (*debilis*) cost in 1347 only a halfpenny. It is strange that for tuition fees as late as 1347 only 4½*d*. a term was paid, as an Oxford University Statute of 1338, while forbidding grammar schoolmasters there to charge more than 8*d*. a term, did so with the proviso "unless he has only one or a few pupils to teach by special agreement." By 1383, as a result no doubt of the rise in wages and scarcity of masters, caused by the Black Death and the French Wars, while the commons of the boys was still 8*d*. a week, a shilling and, in some cases, two shillings a term was paid to the master. One boy paid also a shilling for a master for the summer term "to learn accounts."

In 1403-1404, Mettingham College, a collegiate church in Suffolk, paid 8*d*. a term for each of two boys whom they sent to Beccles School for their education, and 1*d*. a week for a broken term of six weeks only, a normal term being eight weeks, while paying 7*d*. a week for board of one of them. In the Gloucester School

case, reported in the *Year Books* in 1410, an action brought by the two masters of the licensed grammar school against an unlicensed competitor who had set up a rival school, the masters said that the competition had brought their fees down from 2s. to 3s. a quarter to one shilling or less. It was probably the exorbitance of the charge that caused the competition.

When a grammar school was founded at Newland in Gloucestershire in 1445 by Robert Gryndour, it was to be "half-free forever"; that is to say, the master was to take "of scolers lernynge gramer 8*l.* the quarter and of others lernynge lettres and to rede 4*l.* the quarter." Whether we are to infer that 1s. 4*l.* was the normal fee for grammar boys and 8*l.* for boys learning to read, or that the half-freedom was secured by charging the latter only half-fees, is not clear. The Bishop of Norwich had settled the tariff at Ipswich in 1477 at 10*l.* a quarter for grammarians, 8*l.* for psalterians (those learning Latin out of the Psalters), and 6*l.* for primerians, or those learning their primer or elementary Latin grammar. With those learning A B C, called Apesyes, and singing "Songe" the grammar master was to have nothing to do. The town found the tariff too high, as in 1482 they reduced the fees for burghesses living in the town to 8*l.* a quarter and no more. Even so the tuition fees were found so burdensome apparently, that Robert Felaw, the Portman or Mayor, endowed the school and made it free of tuition fees altogether. As the movement for universal free schools was then in full swing, it is difficult to find records of tuition fees after this. All the great endowed schools, from Eton downwards, were free schools. In the next century a rapid rise took place in prices. Thus we find in 1548 a royal ward boarded with one of the gentlemen of the chapel royal paying 21s. 8*l.* for a quarter's board. In 1561 the sons of Sir William Cavendish paid 10s. a week for their board at Eton in a dame's house and 3s. a week as *commensalis* in college, while in 1598 a gentleman at Carlisle paid £2 a year for his son's "quarter's board at Christmas, and for his schooling that quarter 10s." At Winchester in 1619 John, son of Sir Timothy and grandson of Archbishop Hutton, paid 5s. a week for his board as a Commoner. But this was in addition to 4½*l.* for a pound of candles for six weeks and charges for fire, school sweeping 2*l.* and birch 4*l.* Quarterage, *i.e.* tuition fees, were at the rate of 1s. 6*l.* a quarter plus 1s. 4*l.* entrance fee. At Colchester in 1637, though nominally a free school, the freedom was limited to sixteen free scholars, and others paid 10s. a quarter for teaching, 1*l.* for firing, 2*l.* for sweeping, and a pound of candles for lighting. In 1709 the quarterage at Winchester was still the same. In 1731 the ten Commoners in College paid Dr. Burton the amazing sum of £200 a year for their board, which is dear even for the most aristocratic

school to-day, but they were all young noblemen, and he took them out hunting on holidays. The school bill of the first William Pitt, afterwards Earl of Chatham, at Eton in 1719, was £29 0s. 3*l.* for half a year (or at the rate of £60 a year), of which tuition accounted for 7 guineas, *viz.* 4 guineas, 2 guineas to the usher and £1 2s. to the writing master.

At Rugby, by foundation a Free Grammar School, in 1777 the boarding fee was 14 guineas a year. In 1794 the leaving "present" of a guinea and the Christmas present of another guinea were abolished and a tuition fee of 5 guineas imposed. In 1797 the boarding fee was raised to 20 guineas a year; in 1818 it was 40 guineas with 4 guineas extra "for a single bed," and £4 for washing; tuition fees being 6 guineas. At the same time Winchester charged £64 a year, of which 16 guineas was for tuition; Eton £66 a year, of which 16 guineas was for tuition. The total cost of a boy at either was said to be £100 a year. At Eton extra charges were made for noblemen and gentlemen of very large fortune in tutors', as distinct from dames', houses. At Harrow the charge was £125, of which 20 guineas was for tuition. Westminster and Shrewsbury both had the remarkable extra of 5 guineas and 4 guineas for a single bed, making 50 guineas at Westminster and 44 guineas at Shrewsbury with 13 guineas for tuition at the former and 6 guineas at the latter. At the smaller schools, distinctions were made between parlor and other boarders, *e.g.* at Wotton-under-Edge the former were charged 50, the latter 30 guineas, a year; at Exeter the boarders paid 30 guineas, inclusive of tuition, for which day-boys paid 12 guineas at Repton. At Eton, under Regulations made in 1907, the charges for oppidians are £21 entrance fee; and £115 a year for board, £30 for tuition plus £21, practically obligatory, for private tuition, £166 in all. Scholars pay £30 a year. At Winchester the charge for scholars is £21 a year. Commoners pay £127 a year, of which £47 17s. is for tuition. Private tuition is almost unknown. In the cheaper so-called "Public Schools" the charge is from £80 to £100 a year. At the great Day Schools, Cheltenham College charges £36 a year; St. Paul's School, London, £24 9s.; Bedford Grammar School, £16 16s.; Merchant Taylors' School, London, and Manchester Grammar School, £12 to £15 15s.; Bradford Grammar School, £10 to £16; Wyggeston School, Leicester, £7 7s. These are all schools of 500 boys and upwards. The lesser grammar schools charge from £25 to £60 a year for boarders; and from £6 to £12 a year tuition fees. The new secondary schools, maintained by County Councils, charge from £3 to £6 a year, and in the majority of cases the latter sum. But in these schools generally more than half the scholars are freed from fees by various forms of exhibitions and scholarships, and by the regulations of the Board of Education there

must be not less than 25 per cent of free places.

A. F. L.

See FREE SCHOOLS.

**Germany.**—In the medieval town Latin schools the practice grew up for the towns to pay the rector a lump sum by way of salary, but he was allowed to supplement this by customary contributions from the pupils; thus in winter they were expected to provide wood and candles; a small gift was given to the teacher by each pupil at the beginning of holidays (*Austreibegeld*); presents in kind were given at certain seasons of the year, e.g. at Midsummer's Day, Christmas, Palm Sunday, when a cock was given; and as in England the pupils had to pay for the maintenance of the strap (*Rutegeld*). In many cases these presents were commuted into a recognized monetary contribution. Other perquisites belong to the teacher at different times, e.g. free board, income from sale of books, which was frequently protected by the appointing authority against other booksellers, fees from weddings, funerals, and baptisms, collections by itinerant singing, and payment as town notary and scribe. Where a municipality recognized a higher school, German or writing school, it was often the practice for the keepers of these schools to surrender a portion of their fees to the regularly licensed teacher. Fees were paid quarterly, but there was no universal scale or standard. Under the influence of the Reformation it is interesting to notice that the attempt to introduce compulsory attendance at school was accompanied either by the abolition of fees or by a differentiation in favor of the poor. Thus the Leisnig Treasury Ordinance of 1523 abolished fees for inhabitants; so, too, the Halle Church Ordinance (1526); the Brunswick Church Ordinance of 1528 retained fees for the rich, as also did the Ordinances of Brunswick-Wolfenbüttel (1545). The salaries of teachers were provided for in many cases out of the funds of confiscated church property, out of church funds, or out of endowments. Teachers in girls' schools or in vernacular schools frequently received only an honorarium from the local community and charged fees. The Nuremberg Guild of Teachers had a regular scale of charges for writing pupils, non-writing pupils, and private pupils, along with entrance and leaving fees, wood and gifts at New Year, Easter, Pentecost, and Christmas. In Berlin the scale for private schools was 6-9 *pfennig* for spelling, 1 *groschen* for spelling and reading, 1 *gr.* 6 *pf.* for writing and 2 *gr.* with ciphering. In Prussia, by an ordinance in 1717, education was made compulsory and fees were fixed; in 1736 the *Principia Regulativa* provided for the payment of fees by all children between five and twelve, whether attending or not. The scale of charges fixed by the *Generallandschulreglement* (1763) were 6 *pfennig* up to reading, and 9 *pf.* thereafter; a *groschen*, if writing and ciphering

were added. In summer only two thirds of these amounts were charged. The *Allgemeine Landrecht* (1794) attempted to abolish fees and to distribute the payment of teachers among residents according to their wealth. But the payment of fees continued in spite of the law. During the nineteenth century the payment of fees was gradually reduced, and the teachers were paid by the local authorities and supplemented this by fees for church duties as organists and sextons. By the *Constitution* of 1850, Art. 25, instruction in the public elementary schools was declared free, but this provision remained practically a dead letter and the question continued to be actively agitated. An attempt was made to impose fees universally in 1868-1869, but failed. Falk and Bismarck, however, ranged themselves on the side of abolition. While the central authority was in favor of abolition, the district bodies desired to retain them. The law of June 14, 1888, revised on March 31, 1889, abolished fees in the elementary school, and retained them in the *Bürgerschule*, or higher elementary schools. An exception may, however, be made in the case of non-residents attending schools in another district, and where the state apportionment does not cover any extraordinary expenses for the maintenance of fees. In the latter instance the approval of the central authority must be renewed every five years. In Bavaria the cases where school fees are still exacted are decreasing, and they are no longer retained in any of the larger towns. In Württemberg very low fees are charged, while Saxony has by statute fixed a scale of charges according to the type of elementary school (graded or ungraded or higher), the poor being relieved of the burden without incurring themselves any stigma of pauperism thereby.

In the secondary schools fees are universally charged and vary according to the authority maintaining the school, i.e. state or city, the type of school, and the section of the school attended. Thus in the Gymnasium, Realgymnasium, and Oberrealschule maintained by the state the annual fees in the upper classes are 150 M., 130 M. in the lower classes and pro-Gymnasium, and 110 M. in the Realschule and middle schools. In the city schools they vary, being in some cases lower, in some higher, than in the state school. In Bavaria the fees are 45 M. in all types of schools; in Saxony the charges in the Gymnasium, Realgymnasium, and Realschule are 150 M. with some variation, as in Leipzig and Dresden; the fees in Württemberg are 40 M. in the lower section of the Gymnasium and 60 M. in the higher; in Saxe-Weimar the Gymnasium charges 120 M. and the Realschule 80-100 M.; in Baden the fees in state schools are 108 M., while in other institutions there is great variation. In the girls' high schools in Prussia the fees vary from as low as 36 M. to 180 M. a year, the median being about 100 M.; in the middle schools the

average fee is 40.74 M. a year, the general range being from 18 M. to 96 M.

**France.** — The idea of public free education was first seriously agitated during the period of the Revolution. Until then fees were paid universally, except in the few cases where pastors had opened charity schools for children of the poor. The teaching orders also maintained two types of schools, the one well housed and equipped for fee-paying pupils, the other less pretentious and free for poor children. Talleyrand insisted on the principle of free elementary education as the basis of a democracy. There was some proposal in the constitution of 1791 to make education free, but it was not carried out and was withdrawn in 1795 and provision was made by which the schools were to have one third of their places free, a figure reduced in 1802 to one tenth. In 1833 children declared by the municipal council to be unable to pay fees were to be admitted free; this was extended in 1850 to all children who were unable to pay and communes were permitted to maintain free schools. The result was a large increase in free pupils and in the state subsidy, and a decrease in the receipts from fees. Duruy in 1865 proposed the entire abolition of all fees, and in 1867 the communes were authorized, if they desired, to establish free schools and received a subsidy from the state and department. Fees were finally abolished entirely by law of June 16, 1881.

During the early part of the nineteenth century fees were fixed by the municipal authorities; they might be paid in money or in kind or both; and there was a scale according to whether the pupil learned reading, reading and writing, or reading, writing, and arithmetic. Two to six sous, in some cases eight sous, a month seems to have been the usual range of charges for elementary work. For a long time the teachers had personally to go through the indignity and humiliation of collecting the fees in person. By 1833 they were collected in the same way as other town rates. Frequently the fees were supplemented by a salary from the commune, and in 1850 a minimum of 650 *frs.* from fees and salary was fixed.

The fees in the French *lycées* show the greatest diversity, according as a school is in Paris or the provinces, or the pupil is a day pupil, a supervised day pupil, a half or full boarder. The fees for day pupils vary from 40-70 *frs.* in the provinces and 90-100 *frs.* in Paris in the lowest classes to 320-500 *frs.* and 650-700 *frs.* in the highest; for supervised day pupils the fees are from 60-100 *frs.* and 130-140 *frs.* to 380-590 *frs.* and 740-790 *frs.*; for half boarders from 225-400 *frs.* and 500-550 *frs.* to 575-725 *frs.* and 950-1200 *frs.*; for boarders 350-700 *frs.* and 900 *frs.* to 950-1250 *frs.* and 1650 *frs.*

**United States.** — The colonial period opened with the almost universal custom of charging tuition. Besides the income from this source

a salary was frequently guaranteed to the master. In Massachusetts and Connecticut these salaries began at an early date to displace the tuition fees (see FREE SCHOOLS). Among the Dutch of New Netherland and colonial New York a combination of tuition charges and salaries was invariable in the public schools. In other colonies the same custom generally held in the case of schools that were in any sense publicly controlled. Throughout the colonies there was found more or less effort to exempt the poor from the customary tuition fees.

In spite of widely varying conditions the actual tuition charges throughout the whole colonial period were much alike, varying of course with the degree of advancement in learning. At Waterbury, Mass., in 1692, the town meeting fixed the charges as follows: "english: 3:pence Per weeke & for wrighting: 4:pence per weeke & for latten: 6:pence per weeke for each scoller." At New Amsterdam in 1661 the burgomasters thus regulated the elementary school charges: —

"From every pupil quarterly as follows: —

For each child whom he teaches the		
a b c, spelling and reading . . . . .	30 st.	(60 cts.)
For teaching to read and write . . . . .	50 st.	(\$1.00)
For teaching to read, write, and cipher	60 st."	(\$1.20)

The New Amsterdam Latin school at the same time charged six guilders (\$2.40) a quarter. The schools of the S. P. G. (see SOCIETY FOR THE PROPAGATION OF THE GOSPEL) charged fees for those able to pay. The teacher in one of these schools on Long Island (1714) received "5 shillings per quarter (pay) for each scholar." The same rate was charged in a Pennsylvania German parochial school at Lancaster (1747), and in a similar school in Philadelphia (1760).

An indentured servant, sold as schoolmaster in Virginia (1774), charged the same rate for pupils outside of his master's family. Somewhat higher were the rates in the school of the Reformed Dutch Church of New York (1755): "for reading only, 5s.; for reading and writing, 8s., with 6*d.* for pen and ink; for reading, writing, and ciphering, 10s.; for singing, 6s." It is interesting to note that, while in New England rates are frequently given by the week, in the middle colonies they are almost always given by the quarter, and in the Charlestown, S.C., Free School (1712) they are given by the year. Rates in the evening school were higher than for the day school; thus at New Lotts, Flatbush, N.Y., in 1680 the charges for day school per quarter were three guilders for a speller or reader, and four guilders for a writer; while for the evening school the corresponding rates were four and six guilders, respectively. (The guilder in wampum was then worth about eight cents.)

Most of the figures available for the colonial period show simply the ordinary tuition fees. A few others, however, are worthy of note.

In the Philadelphia school (1683), where tuition was four, six, and eight shillings for reading, writing, and ciphering, respectively, we find the statement: "boarding (diet, washing, lodging, and schooling) tenn pounds for one whole year." In rural Pennsylvania (1678-1679) a master agreed with a father to teach his children "to Read ye hybell & if he could do itt in a yeare or a halfe yeare or a quartr. then we was to have 200 guilders." Occasionally in Massachusetts the tuition fee assumed the nature of a town rate with incidental correction for wasting opportunities. Thus at Hadley, Mass., in 1677 "all male children ffrom six yeares oudl to twelve shall . . . pay to the scool such as goe . . . tenn shillings by the year and they that goe not ffive shillings by the year and all others above the age expressed that are found Illiterate and goe not to paie ffive shillings by the year." The custom, common elsewhere, of entrance fees and of stated presents to the master took little or no hold in colonial America. The only instance of the entrance fee noted below the college occurs in Boston (1741), where "entry money" was demanded of "strangers," that is, of non-residents. One quasi-fee, additional to ordinary tuition, seems to have been common in the north, the obligation on the part of the pupils to furnish fuel. The Boston master, of the quotation above made, said, "as to Firing he had not more than Five Shillings apiece" from the pupils. In more rural communities the fuel itself was required. At Flatbush, N.Y., in 1773, each pupil must bring "every nine months a load of wood." (See COLONIAL PERIOD IN AMERICAN EDUCATION.)

With the close of the colonial period a new institution appeared in America, the academy (*q.v.*). Generally these schools charged tuition (even where the elementary schools were free). The Augusta Academy in Virginia (1775) fixed tuition at "£4 per annum for each scholar." Phillips Exeter Academy until 1812 charged no tuition, but in that year fixed its rates at \$3 per quarter. Board in connection with this school was \$2 per week (1799). In 1816 a county academy in Georgia, which taught also the elementary branches, advertised "rates of tuition as follows: Spelling, Reading, Writing, and Arithmetic, ten dollars per annum for each scholar; English Grammar and the higher branches of the Mathematics, fifteen dollars; Greek, Latin, and French Languages, twenty-four dollars, payable quarterly in advance." Board was had at "from sixty-five to eighty dollars per annum." During the '30's the ordinary New England academy charged tuition at from \$3 to \$5 per quarter. In the more rural districts board in connection was advertised at from \$1 to \$1.50 per week. The New York academies are fully reported by the Regents. In 1836 most rural rates of tuition were: for the elementary

branches, \$2 or \$3; for the higher English branches, \$4 or \$5; for the classical languages, \$5 or \$6. Board in the neighborhood varied from \$1.13 to \$3, with a median of about \$1.75. Until the Civil War there was little change in the rural charges, board going up a very little. More high-priced schools, however, entered the field. Even in 1867 there had been little increase in tuition, although board had doubled, averaging now about \$4.50 per week. With the advent of the public high school tuition charges were dropped from public secondary education. The academies which survive are almost exclusively privately controlled preparatory schools. Among the better known are the Phillips Exeter and Andover, and St. Paul's, N.H. The former charge per annum tuition \$150, room \$35 to \$200, board \$140 to \$270; the latter charges \$850 for tuition and residence, besides laboratory and other fees. The more fashionable girls' schools charge higher rates, charges of \$500 being not unusual, tuition and residence often exceeding \$1000.

The philanthropic school societies (see PUBLIC SCHOOL SOCIETIES), which in the early nineteenth century prepared the way for general public support of education, sometimes admitted pay pupils as well as charity pupils in order to remove the stigma attaching to purely charitable institutions. The Augusta, Ga., free school, conducted 'on the Lancasterian system' offered (1821) "the best English education for three dollars per quarter or for nothing according to the pleasure or ability of the party that enters." The New York Public School Society, in trying the same experiment, agreed in 1826 upon the much smaller fees of twenty-five cents per quarter for the three lowest grades, fifty cents for the three next, and one dollar for the three highest grades. Eventually, these pay schemes failed. (See FREE SCHOOLS.)

The history of the gradual displacement of school fees in America by public funds is the history of the public school system. (See FREE SCHOOLS.) Massachusetts led in the movement, abolishing fees from the town schools during the first half of the eighteenth century. Connecticut and New Hampshire soon followed. Elsewhere little was done in this direction until the nineteenth century. So opposed were people in general to the idea of taxation for school support that at first only small appropriations could be secured. Such inadequate funds might be used along one or more of three lines: (1) to pay the tuition fees of the poor; (2) to furnish part of the school support, leaving tuition fees to supply the remainder; or (3) to provide free instruction for all during a term less than the full scholastic year. The first plan has been the initial stage of each developing system. In New England this step was taken in early colonial days; elsewhere not until the nineteenth century. Pennsylvania, for example,

from 1802 to 1834 had a state policy of this kind. In the South it was the usual form of state support of elementary education until the Civil War. The second line of procedure, which combined public support with tuition fees, in effect lessened the fees of all. This was in many places a second stage in the evolution of public support. New York State combined this plan with the preceding (and with the succeeding) until 1867, the proportion of school funds raised by "rate bills" (tuition fees) dropping from nearly all at the inception to 60 per cent by 1836 and to 9 per cent by 1867, when the schools were made entirely free. It may be added—strange as it seems—that the proportion of school districts in New York which gave free tuition to the poor declined from above half in 1819 to only one in four by 1867. The third plan, that of keeping a shortened session absolutely free, was early devised in colonial Massachusetts, where it remained the rule until the Horace Mann revival. In most of the states this too has formed a transition to the complete public school system. In fact, many of the states may be said even yet to be in this transition stage.

The colleges during the colonial period made but small tuition charges. At William and Mary the charges were "20s. entrance and 20s. a year for Pupilage for each scholar" (1724). Until 1810 the charges at Yale did not exceed 33s. From that time they have gradually increased: \$33 from 1810 to 1852; then by stages of \$38, \$45, and \$60 to \$90 in 1870; from 1874 to 1887, \$140; since 1887, \$155. Harvard in 1833-1834 published fees as follows:—

Instruction, Library, Lecture-room, Steward's Department, rent and care of rooms . . .	\$90.00
Board for 12 weeks at \$1.90 . . . . .	79.80
Textbooks . . . . .	12.50
Special repairs, etc., about . . . . .	3.00

In 1864 the first of these items was broken into \$75 for tuition charges and \$15 for "rent and care of rooms in the college building." Since 1869 tuition fees of \$150 have been exacted. Wide diversity prevails at present among American colleges in regard to fees. The state universities for the most part charge nothing except for law and medicine. Privately endowed institutions generally exact fees, though a very few (*e.g.* Leland Stanford) charge nothing except in the professional schools. The amount of the fees exacted is roughly correlated with the financial strength of the institution. Those institutions whose invested funds fall below a half million of dollars group, in the matter of tuition fees, about a central tendency of \$45 or \$50 a year; where the invested funds lie between a half million and two millions and a half, the central tendency of fees is \$90; for universities whose funds are above two and a half millions, the fees group about a central tendency of \$125.

In the last case all those having funds exceeding five millions (except Leland Stanford) charge about \$150. The figures just given apply to fees in the purely literary department only; in the vocational courses (law, medicine, engineering) the fees generally run higher, the maximum being \$250 in medicine and engineering (Columbia, Massachusetts Institute of Technology).

Besides tuition fees, charges are ordinarily made in the laboratory courses for materials. A matriculation fee, perhaps of \$5, is paid once. Gymnasium fees of from \$5 to \$10 are often exacted. A diploma fee of \$5 or \$10 is usual. For the higher degrees examination fees are often charged, amounting sometimes to \$35.

Two fairly distinct but opposing tendencies seem to emerge from the foregoing discussion. On the one hand, privately endowed institutions, principally in the East, have during a long period of years been increasing their fees, apparently as much as they can without unduly cutting down attendance. On the other hand, the state, principally in the West, has been taking over more and more of education, with the consequent elimination of fees from the elementary school up through the university.

**FELBIGER, JOHANN IGNAZ VON** (1724-1788).—A prominent educator in Silesia and Austria. After studying theology at Breslau, he joined the Augustinian Order at Sagan in Silesia, where he subsequently became abbot, and had oversight over the churches and schools. His interest in education was aroused by the

necessity of reforming the schools under his supervision and by the *Reports* issued by the Berlin Real School, established by Hecker (*q.v.*). He visited the school at Berlin, and was struck by the provision there made for the training of teachers, and by the tabular and alphabetic method employed by J. F. Hältn, one of the teachers of the school. On his return he sent young men to be trained at Berlin, and himself set about the work of reform. He founded a number of normal schools, taught personally, issued textbooks and catechisms, and improved the material conditions of the teachers. In 1765 he drew up, at the request of Frederick the Great, the *School Regulations for Roman Catholics in the Duchy of Silesia and the County of Glatz*. He introduced better teachers, minimized rote work, insisted on simultaneous instruction and uniformity of instruction. For these ends he issued tables dealing with different subjects in their divisions and subdivisions. These tables were placed or hung before the class, and all the pupils could be employed on the same thing at the same time. The alphabetic method was a mnemonic device by which initial letters of words or sentences were memorized for purposes of recall. In 1774 Felbiger was summoned to Austria by Maria Theresa as General Director of the School System of the Austrian States, and laid the foundation of the present Austrian system; he repeated the work which had been so successful in Silesia, and now exercised great influence throughout Catholic Germany. His activity was cut short by his retirement in 1780 by the orders of Joseph II, who limited him to the Hungarian schools. The strength of Felbiger was his insight into educational needs; the defects of his systems were the introduction of extremely mechanical processes of administration and instruction. Felbiger died at Pressburg in 1788. His chief works were *Forderungen an Schulmeister und Lehrer der Trivialschulen (Directions to Schoolmasters and Teachers of the Primary Schools)*, *Eigenschaften, Wissenschaften, und Bezeigen rechtschaffener Schulleute (Qualities, Knowledge, and Characteristics of Proper Schoolmen)*, and *Methodenbuch*.

FELLENBERG, PHILIPP EMMANUEL VON (1771-1844).—Swiss philanthropist and

educator; born at Berne of a noble family. His father was a man of considerable learning, and his mother was imbued with a deeply religious spirit. Under such influences, to which was added the pitiable condition of a large part of the Swiss population at that time, it was not surprising that Fellenberg devoted himself to educational reform. For him the only means for the moral and economic improvement of a country lay in education. His early efforts were directed to the education of his own children, to whom he soon added a few others. In 1807 he founded the Literary Institution or Academy, in which the children of nobles and gentry were to be received. The Fellenberg home was close to Neuhof, and an intimacy sprang up between the older Fellenberg and Pestalozzi, in which the son soon joined. Not only was he stimulated by Pestalozzi's ideas, but his father had delivered an address before the Helvetic Society on *The Necessity of Improving National Education*, which encouraged him to apply himself to a study of education. The age, too, was one of philanthropic and humanitarian movements, and several experiments had already been made in his own country, with which he was familiar; and a literature on the subject had sprung up under Basedow's influence. In 1799 Fellenberg purchased an estate at Münchenbuchsee, which, under the name of Hofwyl, was to become widely known. In 1804 he undertook the education of some poor children, and associated Pestalozzi with the work, but the overpowering administrative routine and executive thoroughness of Fellenberg were too much for the great teacher, whose only guides were sympathy and affection. An effort made in 1817 to combine forces failed for similar reasons. Fellenberg's charity school did not meet with great success until it was placed in the charge of Wehrli (*q.v.*) in 1808, and developed into the agricultural or poor school. A normal course for Swiss teachers was introduced during the summer vacation entirely at the expense of Fellenberg, but through some jealousy the Berne teachers were soon forbidden to attend. A real intermediate or practical school for the children of the middle classes was founded in 1827, while in 1823 Fellenberg's wife had already founded a school for poor girls, which was under the charge of a daughter of the founder. The ideal which Fellenberg set before himself was to realize such a system as Pestalozzi had indicated in his *Leonard and Gertrude*, and in 1807 he called on his contemporaries to follow Pestalozzi's plan. The aim of his institution was "to develop all the faculties of our nature, physical, intellectual, and moral, and to endeavor to train and unite them in one harmonious system which shall form the most perfect character of which the individual is susceptible." He emphasized the need of vocational preparation in all grades of society; upright and noble leaders were as necessary as reliable and honest

followers. While the individual bent was to be followed in the choice of vocation, satisfaction with one's station in life was as important a lesson as any other work of the school. And in this way the vocational preparation was to be combined with moral and religious training. Educationally, too, Fellenberg regarded manual activity as the necessary complement to the sense perception and object teaching of Pestalozzi. Thus the most significant feature in these schools was the provision for manual labor. Hofwyl was an estate with an area of six hundred acres. The chief occupation was agricultural, not only for its physical and moral influences, but to defray the expenses of the institution. For the poor children such work was frankly vocational; for the pupils in the Literary Institution the aim was to prepare those who would some day have estates of their own to acquire an intelligent interest in their management. In addition to this occupation there sprang up other industrial employments, e.g. the manufacture and repair of agricultural implements, a printing establishment, the making and repair of clothes, and other work which a large institution daily called for. The pupils of the poor school were kept up to the age of twenty-one, and their studies included, besides reading, writing, and arithmetic, drawing, singing, natural history, geography, history, geometry, and mensuration, botany, agriculture, hand-work, and religion. Some of these pupils were later promoted to the higher departments and trained as teachers. In the higher school a reformed curriculum was introduced, retaining the classics, but also emphasizing modern languages, sciences, drawing, music, and the practical work. Physical exercise and military drill formed an important part of the work of all pupils in the institution. But, above all, Fellenberg laid emphasis on religious and moral education. While religion was regarded by him as a basis for morality, he did not neglect the moral training which comes from social contacts. The institution on a small scale was a copy of society, with its class divisions, which Fellenberg accepted as divinely ordained, and the individual was but a member in it; hence the relations between the pupils were important for the formation of moral character. For a time a system of self-government was tried, but was abandoned. On the whole, Fellenberg relied on the influence of example, strict vigilance, and the complete eradication of the slightest corrupting influences. Rewards and corporal punishment, in so far as these are external forms of stimulus, were not employed; true work was its own reward, and a boy who merited corporal punishment had no place in the institution. From Hofwyl colonies were sent out to neighboring districts; the best known of these was the colony of thirty boys which was settled in 1816 at Meykirch, about six miles from the central institution. After the death of the founder

in 1844, the charge of the institution devolved on his elder son, William, who associated W. B. Mönnich with himself as director of the Literary Institution and the Real School. But one school after another had to be closed, until, by 1848, none remained. In 1884 the cantonal normal school was moved from Münchenbuchsee to Hofwyl.

The Fellenberg movement exercised a great influence on education in Europe and America. Among the pupils of the literary institution were found princes and nobles from most of the European countries. From America came Robert Dale Owen, the son of Robert Owen (*q.v.*). The institution was almost as famous internationally as that of Pestalozzi at Yverdun. As early as 1816 Lord (then Mr.) Brougham (*q.v.*), in giving evidence before an educational committee, referred in high terms to the work of Fellenberg, and led to some articles on the subject in the *Edinburgh Review*, Vols. XXXI and XXXII (1817 and 1818). About 1835 George Edmondson opened a school at Queenwood Hall, Hampshire, where he gave instruction in agriculture, maintained science and technical departments, a blacksmith's shop, and printing press, and emphasized practical instruction. Professor Tindall (*q.v.*) was one of his teachers, and Henry Fawcett (*q.v.*) one of his pupils. The most notable influence which came from the Hofwyl institution was not on the moral or intellectual side, but took the form of the manual labor movement in America, in which many colleges had their origin and in which may be traced the system of working one's way through college.

**FELLOW OR FELLOWSHIP; SCHOLARS AND SCHOLARSHIPS.** — England. —

In the original English usage the term "fellow" was used in the universities of Cambridge and Oxford as equivalent to the Latin *socius*. Fellowship thus was applied in the literal sense, as "the spirit of equality and companionship which should prevail among the recipients" of benefactors' bounty. In the statutes of Merton College, Oxford, followed by many other colleges, the founder decreed that the college was to be called the House of the Scholars of Merton. The college was designed mainly for students in arts or philosophy, who would pass on to the study of theology "at the award of their Warden and Fellows" (*i.e. socii*), though permission might be given

to four or five to be students in canon law, or even civil law. A grammarian was to be appointed to whom not only students in grammar, but also any of "the scholars," might have recourse to obtain instruction "in the Latin discourse or idiom." The number of scholars was to be dependent on the financial resources of the house, but each scholar was to receive annually fifty shillings (from which was to be deducted the cost of commons). The scholars were to be divided into classes of twenty, or ten, if necessary; and the discreetest of the scholars were to be chosen as præpostors or deans over the rest, and to act as coadjutors of the warden in "the care of the younger sort, and as to their proficiency in study and good behaviour." These præpostors were to have a somewhat more liberal allowance than the other scholars. Moreover, in every chamber in which scholars resided, one was to be chosen of more mature age than the others, "to have a superintendence over the other fellows." Throughout these quotations from the Merton Statutes, it will be seen that the students are "scholars" in relation to the college, and "fellows" in relation to one another. Whether senior or junior, all were called scholars, and in the whole body, warden and scholars, whatever their standing, was centered the whole control of the college. The colleges, consisting of secular students in training as secular clergy, became incorporated bodies, exactly parallel to the monasteries of regulars, and came to acquire "a share of that influence in the University which the establishment of powerful monasteries had almost monopolized in the hands of the Regulars, and wicking that influence for the benefit of the church in the advancement of the secular clergy, who for lack of support and encouragement in the Universities, were sadly decayed in learning." From a papal bull of 1280 it appears that Merton College was founded for forty scholars. Vacancies occurring were to be filled up by the unanimous vote of the warden, and at least six senior scholars, candidates of the founder's kin or those coming from a diocese in which the college held property to have the preference. All the scholars were required to dine together in the refectory, and one of the scholars was to read aloud in Latin during meals. The warden received fifty marks a year for his table, and had allowances for servants, wardrobe, and horses. Once a year he had to ride to examine the different estates belonging to the house, receive the rents for the past year, and fix them for the coming year. There were a vice-warden, three or four chaplains, three bursars, and five auditors of accounts, besides the deans. Attendance was required, "as far as their leisure serves," at the canonical hour of celebration of masses on holy and other days. The founder makes quite clear what he means by a fellow in the following article of the statutes: "Also the

Fellows of the Society, as they were *fellows* in the intercourse of life to their lives' end, are in like manner, at their death, to have ecclesiastical burial among their fellows and brethren."

The scholars could retain their places so long as they did not break the rules by misconduct, or accept a benefice, or become regulars. They filled up the vacancies in their body, however numerous they might become, through increase of value of the estates left. Finally, to show how self-contained and self-governed the house was, in the election of the warden, seven of the senior scholars were to ask for nominations of persons "belonging to the House or elsewhere," from all the scholars; then having heard all they could as to the "energy, probity, and honour" of each suggested name, to choose the best three and to give in these three names to the visitor who was to make the final choice. Originally, then, the college was the body made up of the warden and the scholars, all living on the foundation, with allowances as settled by the statutes, living there ordinarily to study all their lives, unless they should be preferred to a benefice. They were all members of the society or house, therefore all *socii*, all fellows of one another.

About 1361, Simon Islip, Archbishop of Canterbury, founded a new college, called Canterbury College, at Oxford. The warden and three of the twelve fellows were Benedictine monks, the other eight being secular students. In 1365 the archbishop ejected the warden and the three monks, and substituted four secular scholars. The new warden appointed was the famous John Wyclif, and about the same time new statutes were drawn up. These statutes were devised to encourage graduates to pursue higher studies, rather than undergraduate work. The statutes show "how thoroughly the inmates of Canterbury College were regarded as members of one family, the term 'fellow' being still used in its original sense of comrade. The fellows were to dress alike, to attend mass together in the early morning, to go together to the schools, accompanied by a servant who should carry their books, to take their meals together, to go out walking in couples after vespers, and at night to occupy four or five common dormitories." Wyclif and his fellows were ejected in 1370. No length of time was prescribed in the statutes for a scholar remaining in the college. It was a time of preparation for clerical life, in the first place. A boy came to the university, say at fourteen years of age, and the stages by which he attained to the highest degree in divinity and became a priest ran parallel, and both aims might be attained by twenty-five years of age. The scholars needed means of subsistence, to reach this double end, even if they went through all the stages normally, between fourteen and twenty-five years of age. But as they would vary in length of time, no limit was fixed. Moreover, although scholars

might achieve their academic and ecclesiastical aims, yet, if no promotion were available, the scholars or fellows could hardly be turned out of the colleges on that account. Accordingly, as Huber supposes, the practice was established for the fellows to retain their allowances and residence until they obtained some benefice. Huber continues: "In the political tempests of the fifteenth century, nearly all other stipends disappeared and the whole academic population diminished, the College-Fellows became gradually the actual stem of the University. They generally became masters, and in fact applied themselves to the business of teaching, and succeeded to the authority of the ancient Teacher-Aristocracy." The tendency for the older students to need maintenance for longer periods made a differentiation of the fellowship as applied to the allowance to the older members of the foundation, and was transformed into a life maintenance for post-graduate distinguished students — and the term "fellow" specially applied to each, while the term "scholar" was given to the younger students on the foundation. At the Reformation, fellows had to show their acquiescence in the Protestant doctrines, but otherwise there was a survival of old custom, with regard to attendance at chapel and hall, and even as to celibacy. In both Oxford and Cambridge in the statutes of most colleges, fellowships were restricted to natives of particular counties, or dioceses; in some cases they were limited to those who came from certain schools. Sometimes they were chosen by seniority from the scholars; sometimes preferentially to be from the scholars. Sometimes fellowships were obtained by purchase. Sometimes they were conferred by mandate of the sovereign, but not without keen resistance by the university from 1577 onwards. (See Mullinger's *History of University of Cambridge*, Vol. II, p. 286, *et seq.*)

Similarly Sir Walter Mildmay, in founding (1584) Emmanuel College, Cambridge, the first Protestant foundation, endeavored to resist the growing practice of fellowships becoming a life maintenance. Though he included the restriction of vacating the fellowship within a year of admission to the doctor's degree, King Charles I arbitrarily overruled the statute, and Emmanuel College had to fall in line with the other colleges in 1627; and though the Long Parliament, in 1641, declared King Charles I's dispensation illegal, it does not seem that their action had much effect. Mullinger (*History of Cambridge University*, Vol. II, p. 387) says of the first half of the seventeenth century: "There is indeed only too good reason for concluding that the award of a fellowship solely on the ground of merit was the exception rather than the rule; and even the outgoing fellow generally contrived to obtain a certain consideration, as the price of the exertion of his influence in favor of a successor." In 1619 John

Hall, (*q.v.*), in his *Humble Motion to the Parliament of England concerning the Advancement of Learning and Reformation of the Universities*, advocates the reduction of those "Friar-like Lists of Fellowships" into a fewer number, and those retained to be given to specialists who may act as professors, and pursue original investigations on the one hand, and to others of "more patient heads" who shall instruct whoever come for instruction; and perhaps a third kind, for those "worn out with contemplations and those greater labors of the mind who might thus sit warm and know nothing less than necessity in their honored old age." "Six fellowships thus awarded," says Hall, "would do more than six score at this present do." The late Professor J. E. B. Mayor, in his *Life of Matthew Robinson* (p. 28, note 1), states on the authority of Calamy that there were fellowship examinations in 1650, which included versification, *viva voce* questions, and other exercises. But the examination apparently could be overruled by party spirit and personal considerations. Wordsworth, in *Scholae Academicæ* (p. 344), notes that when Richard Bentley, in 1700, became master of Trinity College, Cambridge, he found that the custom was to examine candidates for fellowships (and scholarships) in the chapel *viva voce* before the master and senior fellows. Wordsworth reprints (*ibid.*, p. 348), the earliest Trinity College Cambridge examination papers he has seen, which included questions historical, geographical, and grammatical (three separate papers). He also summarizes the views of Dr. Richard Davies, late fellow of Queen's College, Cambridge, as given in his *General State of Education in the Universities* (1749), in which Davies proposed to abolish "close" fellowships and scholarships, to terminate fellowships ten years after the first degree, and to sequester sufficient fellowships to provide for at least fifty professorships in each university, to be remunerated, in part, according to the attendance of pupils.

In the eighteenth century, and even in the nineteenth century, fellows once on the foundation remained on it for life without performing any services, and often were perpetual absentees from their colleges. After University Commissions in 1850 and 1877, new statutes were drawn up for the colleges, taking away, ordinarily, restrictions as to place of birth and relationship to founders, etc., and limiting the tenure of ordinary fellowships usually in Cambridge to six years and in Oxford to seven years. The conditions of election vary in the two universities, and in the different colleges of each university. For instance, at St. John's College, Cambridge, under the statutes of 1882, celibacy is no longer imposed as a condition. The length of tenure is six years. The emolument is about £200 a year to each fellow. The number of fellowships is fifty-six, of which five are reserved as professorial fellowships, about thirty

are tenable in conjunction and in addition to their salaries as holders of college offices, *e.g.* bursar, tutors, etc., and at least twenty-two are available as ordinary fellowships. The election is vested in the council (*viz.* the master together with twelve fellows of at least three years' standing from their first degree, who shall be elected from time to time by the master and fellows of the college), who may call in other fellows or outsiders, to help to ascertain the qualifications and proficiency of the candidates. The electors, severally, must make the declaration: "I do solemnly declare that I will vote for that person who is, in my judgment, the most fit to be a fellow of the college, as a place of education, religion, learning, and research." The five professorial fellowships at St. John's College, Cambridge, are reserved as additional emoluments to professors of the University of Cambridge, and are in addition to the fellowships, which are bestowed on holders of official positions in the college, who do not vacate their fellowships by lapse of time. A fellow, at St. John's College, who has served the college for twenty years in some official position, may, under provisions specified, hold his fellowship for life. The fellows of a college in Cambridge are ordinarily chosen from amongst graduates of that college, but the electors usually have power to elect a graduate from any other college in the university, and generally from any college in either the university of Cambridge or Oxford. In Cambridge colleges the election to fellowships is ordinarily made without any further special examination *ad hoc*, though the contrary practice prevails at Oxford, where graduates of one college may try for fellowships at other colleges, and present themselves for fellowship examinations either in their own or in almost any other Oxford college. At Peterhouse, Cambridge, the statutes give power to elect to one fellowship, or more, a person "eminent for science or learning," whether a graduate of Cambridge or Oxford, or not. At Gonville and Caius College, Cambridge, it is explicitly stated that the governing body has power, in electing a fellow, to attach any special condition to the tenure of his fellowship, which may seem to them desirable in the interests of the college. In the past fellowships have been held free from any specified or even implied obligation to conduct any special research, or to teach, or to write a book. The college was a corporation taking steps to provide for its perpetual continuance, through a succession of fellows. It insisted on an atmosphere of loyalty to all the traditions of the foundation and its developments, and relied upon the exercise of general personal influence rather than any literary output. The development of scholarship, though not explicitly demanded, became part of the tradition, and any dignified and outstanding work done by a fellow was welcomed as adding to the wealth of the college tradition.

But, notwithstanding the great variety in the conditions of award, the unanimous tendency in the colleges of both universities now is to award ordinary fellowships on and for research work, and not merely as prizes for good academic work. There is an implicit undertaking on the part of fellows to promote in some real, though not usually defined way, the advancement of learning. There is, sometimes, the explicit understanding that the elected fellow "continue to promote his researching" in some definite study.

In the Oxford colleges fellowships are usually awarded after a competitive examination, and, as already stated, candidates are received ordinarily at different colleges from that of which they have been members as undergraduates. All Souls' College at Oxford is a college in which there are no undergraduates, so that it consists solely of a warden and fellows, with two chaplains and clerks. Provision is made for forty fellowships in all, some open, and some reserved for special purposes. At Magdalen College, Oxford, the fellowships (by the statutes of 1882) are to number not less than thirty nor more than forty, under the same conditions as All Souls'. In addition to the college fellowships, there are at Oxford two Craven university fellowships and three Radcliffe traveling fellowships. For the Craven election may be made with or without examination. The fellowship is tenable for two years, and eight months of each year of tenure must be spent abroad in study in some place approved by the electing board. The Radcliffe traveling fellowships are awarded to encourage the study of medical science, and the fellows are required to study abroad.

The newer universities in Great Britain, Manchester, Liverpool, Birmingham, Leeds, Sheffield, and the University of Wales, all have fellowships, usually of the value of from £100 to £150 a year, awarded to recent distinguished graduates to undertake special specified research work, in Great Britain or abroad, for one, two, or three years. In these awards statement of the proposed subject of research is made by each candidate, and the pursuit of the research is obligatory on the elected fellow, in the place (at home or abroad) agreed upon by the electing board of the university and himself.

In the Scotch universities there are many fellowships, with many varied conditions, all or nearly all awarded on examinations *ad hoc*, or on dissertations, or on both. They are usually tenable for three or four years, and vary in value from about £80 to £200 a year. In the Shaw Fellowship in Mental Philosophy in the University of Edinburgh, the holder may be required in the fourth or fifth year of tenure to deliver a course of four lectures in that university, though graduates of any Scotch university may compete for the fellowship.

In the University of Dublin (founded 1791) the conditions for fellowships were founded,

originally, on the usage of Trinity College, Cambridge. There is a Provost and seven senior fellows, in whose hands chiefly is the administrative side of the college. There are twenty-six junior fellows, of whom fifteen are tutor fellows. Junior fellowships are awarded on examination. There are no conditions of research imposed, but in course of time they ordinarily lead up to tutorships, if the fellow remains in the college. The senior fellowships are chosen from the junior fellows, and the offices, which are conjoint, are valuable appointments. In the new Royal University of Ireland junior fellowships are of the value of £200 a year, for four years, in which no teaching must be undertaken. They are awarded often amongst graduates of two years' standing.

#### SEE EXHIBITIONS; SCHOLARSHIPS.

**United States.**—In the United States a fellowship is now an appointment ordinarily, for a single year, carrying a stipend to enable a student to complete the requirements for the Ph.D. degree, or less frequently for advanced professional work. It is not, as it still is in England, a more or less permanent title, and the fellow here has no voice in the government of the institution. Traces of the older meaning may still be found; for example, the corporate title of Harvard University is "The President and Fellows of Harvard College."

The first American fellowship, in the present sense of the word, was the Macy fellowship established in 1865 at Yale. This was followed in 1868 by the Harris fellowship at Harvard. The real beginning of the fellowship system, however, came in 1876, when twenty university fellowships were established at Johns Hopkins, each bearing a stipend of \$500, less tuition.

The establishment of a fellowship has become a favorite form of bequest or memorial gift, partly because there are comparatively few permanent uses for funds too small to endow professorships or erect buildings.

The present development of the system may be seen from a report, made in 1906 by President G. Stanley Hall of Clark University, regarding the fellowships and scholarships available in the institutions, at that time members of the Association of American Universities: California, Catholic, Chicago, Clark, Columbia, Cornell, Harvard, Johns Hopkins, Michigan, Pennsylvania, Princeton, Stanford, Virginia, Wisconsin, Yale. Of these, Stanford has no fellowships. The others give a fairly accurate picture of the conditions throughout the United States, though it must be remembered that most of the more richly endowed and supported institutions are included in this list.

The distinction between fellowships and scholarships is very confused, and the conditions of award and tenure are far from uniform. In many cases this is due to the technical wording of bequests. In the following statistics any appointment of an annual value of \$350

plus tuition charges, if any, has been included among the fellowships, and any appointment with a smaller stipend among the scholarships. Bringing President Hall's figures up to the year 1911, the total number of fellowships in these thirteen institutions is 272, of a total annual value of \$139,250, about half of which comes from special fellowship endowments and half from general university funds. The total number of graduate scholarships exceeds 400.

The total annual appropriation for fellowships and scholarships, including the scholarships available in the professional schools and in the undergraduate college, makes no inconsiderable item in the university budgets. At Harvard and Columbia it amounts to more than \$100,000 per annum.

The fellowships range in annual value from \$100 to nearly \$1500, the stipend of the Johnston appointments at Johns Hopkins. The normal stipend is perhaps \$500. In endowed institutions where tuition fees are charged, the amount is naturally higher than in the state institutions where tuition is free, and the fellowships in the city universities, with their high living expenses, are likely to be larger than those in the rural institutions. Nowhere is there found as elaborate or as highly endowed a system as that for the Rhodes scholarships, which, so far as the American scholars are concerned, is practically a fellowship system.

The figures given above do not give the total aid rendered in these institutions to candidates for the doctor's degree. It is usually tacitly understood that assistants are to devote a considerable portion of their time to graduate work, for which no tuition fee is charged. Advanced work is also done under grants from the Carnegie Institution and other similar endowments, or in separate institutions, such as the Rockefeller Institute. Men on permanent appointment in smaller institutions, too, are often given leave of absence on half pay to enable them to complete the work for the doctor's degree at one of the universities.

Appointments to university fellowships and graduate scholarships are announced publicly, and the appointment is regarded as part of the academic *vita* of the incumbent. Provision is always made for a student of high academic promise who does not need financial aid, to retain the title while waiving the stipend.

Of the 272 fellowships cited above, 58 only are limited to the graduates of any particular institution. Classified in another way, about one third of the fellowships are attached to specific departments or divisions of study, and two thirds are not so restricted. In the latter case there is ordinarily an informal distribution in order that no group may be left entirely without a representative. The limited appointments are ordinarily in fellowships provided by special endowment, and the unlimited in those supported from the general university funds.

## FELLOW OR FELLOWSHIP

In a few cases it is stipulated that the incumbent shall study abroad, and in many others he may do so by special permission. The number of Americans, however, who wish to study in Europe for a full year or longer is decreasing, and a considerable number of these obtain Rhodes scholarships.

There are many interesting individual endowments, for example, a fellowship in American archæology at the newly founded University of Mexico. Several of the large chemical and other industrial corporations maintain research fellowships. This type of fellowship has been particularly developed at the universities of Michigan, Kansas, and Pittsburg. At Illinois there are ten \$500 fellowships in experimental engineering. At Amherst college there is an interesting endowment known as the Kellogg fellowship, tenable for seven years, the first three to be spent at a German university and the last four as a lecturer at Amherst.

Whether a fellow shall devote his entire time to study is a moot question. At Columbia this is insisted upon. At Harvard, on the other hand, there are thirty teaching fellowships, and at Wisconsin a teaching fellowship is attached to each important state high school, the incumbent receiving \$225 from the university and \$100 from the school.

There is a growing feeling that under present circumstances the providing of fellowships is overdone, and that teaching, like the ministry, is harmed rather than promoted by paying mediocre men to enter it as a profession. "It takes more energy to stop studying and go at something else, than to go on studying. Many of our graduate students have no other momentum than this inertia" (Slosson). Careful organization for student employment at the stronger universities and the many loan funds have certainly lessened the need for direct aid. The weight of academic opinion, however, is still in favor of retaining the fellowships and scholarships now open. The list of the Johns Hopkins fellows, with its high percentage of names distinguished in American scholarship, is often cited by the supporters of the present system.

One very general weakness in the system, particularly among the endowed universities, is the inadequate provision made for women. Most fellowships were established before women entered graduate work in large numbers, and the regulations have not been modified to meet the changed conditions of to-day.

With this exception, careful provision is generally made for the judicious award of fellowships through previous written application and reference to departments and committees. Uniform dates for application, notification, and acceptance are now set by most of the members of the Association of American Universities, to prevent the candidate from playing one university against another and

## FENCING

from breaking his agreement should a later and more desirable appointment come to him. In the stronger universities the applications are so numerous, and the difficulty of getting real information about a stranger so great, that practically all appointments go to men already in residence, and, therefore, personally known. The scholarships are counted upon to get in new blood.

**FENCING.**—One of the oldest forms of exercise used in the physical education of the young. In the form of sword play, it constituted an important branch in the education of the young knights. Fencing is the national sport of the French people, as cricket is the sport of the English and baseball the national sport of America. The sword play of the Middle Ages was practiced with heavy weapons, the fencer holding the sword in one hand

and a shield in the other. During the nineteenth century, the art of fencing was greatly developed; the heavy sword was replaced by several lighter, weapons, as follows: the sabre or broadsword, similar to the old sword, only lighter the foil, the dueling sword, and the baton or singlestick. The foil is the weapon most extensively used to-day by those who indulge in fencing as a sport. It is not a real weapon, in that it is not used either in war or in dueling. The light sabre, dueling sword, and singlestick are also used to some extent by amateurs of fencing as a sport.

As an exercise, fencing is especially valuable for developing good carriage, grace of movement, agility, and the ability to think and act quickly. In addition to these important physical accomplishments, there are definite ethical and social qualities fostered by this sport. The traditions of chivalry and courtesy always associated with fencing give it the distinction of being *par excellence* the sport of gentlemen. Fencing is the only combative sport adapted to girls and women. The graceful positions and movements characteristic of this exercise, and the polite and gracious formulas exchanged by the contestants, make it particularly attractive to women.

In the United States, the men's colleges have held annual competitions for the intercollegiate fencing championships since about 1890. More recently the women's colleges have taken up the sport with enthusiasm. The best results are obtained from individual instruction, but some teachers have succeeded in teaching the elementary movements of lunging, simple attacks, and parries to large classes arranged in double lines. G. L. M.

**FÉNELON, FRANCOIS DE SALIGNAC DE LAMOTHE** (1651-1715). — French prelate and author. While director of the institution of the *Nouvelles Catholiques*, founded for young women converted from Protestantism, he wrote his *Education des Filles* (1687) for the Duchess de Beauvillier. This work is one of the earliest attempts at a systematic discussion of the education of girls, which the author claimed had been too long neglected. The main thesis is that "women are weak, but must be strengthened for duties that lie at the foundation of all human life." It is their moral influence as mothers and homemakers that gives importance to their education. Fénelon takes up the position that there is much that they cannot learn, but in addition to a deep religious training, girls should be taught reading, writing, and arithmetic, music and painting, for the cultivation of taste, and the management of homes, economy, neatness, and order. Much in this work, however, is of general application to the upbringing and education of children. His chief works of a pedagogical character were written as a result of his appointment (1689) as preceptor of the young dukes of Burgundy, Anjou, and Berry,

grandsons of Louis XIV. These were: *Recueil des fables composées pour l'éducation de Mgr. le Duc de Bourgogne*; *Dialogues des Morts*; and *Télémaque* (1697-1698). Fénelon's constant efforts to "diversify" instruction, which were indisputably for the purpose of relieving the pupil of effort and of making his studies attractive and easy, are evidence of a conception of the place of interest, of a poor type perhaps, in instruction, his theory being that "everything that delights the fancy facilitates study." He was a staunch supporter of public education, contending that the children belonged less to their parents than to the State, and that they should therefore be educated at public expense. For editions of his complete works, see Gasselin et Caron (34 vols., Paris, 1820-1830), and Leclère (38 vols. Paris, 1827-1830). For portrait see opp. p. 307.

**FERMAT, PIERRE DE** (1601-1665). — A famous French mathematician. He was born at Montauban in 1601, and died at Castres, Jan. 12, 1665. He was a public official at Toulouse, mathematics merely occupying his leisure time. He published only a few papers, but he left a mass of notes that show a remarkable genius in the field of the theory of numbers (*q.v.*). He prepared an edition of Diophantus (*q.v.*). It is probable that he had, in his own mind, worked out some of the principles of analytic geometry (*q.v.*) before Descartes published *La géométrie* (1637), but he published nothing upon the subject and he destroyed some of his original manuscript, before his death. With Pascal he laid the foundation for the theory of probabilities. One of his best-known theorems is that no integral values of  $x, y, z$  can be found to satisfy the equation  $x^n + y^n = z^n$  if  $n$  is an integer greater than 2. This has never been proved, and at present there is a large fund awaiting the one who shall demonstrate it to the satisfaction of the University of Göttingen. D. E. S.

**FERRAR, NICHOLAS** (1592-1637). — Founder of an Anglican community at Little Gidding. He went to school at four, and at five could repeat a daily chapter in the Bible. In 1606 he went to Clare Hall, Cambridge, took his B.A. in 1610, and remained three years further as fellow. From 1613 to 1618 he traveled and studied in Germany and Italy. On his return he was active in connection with the Virginia Company, and on its failure determined to retire with his relatives, to the number of forty, to Little Gidding, where the community lived on a plan organized by Ferrar. Next

after the church, the school occupied his attention. An ancient dovecote was enlarged into a handsome schoolhouse, and permission was given to children from neighboring parishes to attend. They were taught, without fees, reading, grammar, writing, arithmetic, and music, and the principles of the Christian religion, the pupils spending part of the day "in perfecting their harmonies in the scripture or getting it by heart. Some of them exercised their diligence in gilding and binding of books, and for that purpose Ferrar entertained a Cambridge book-binder's daughter to show them that piece of skill." Three masters were engaged to teach English, music, and writing. Ferrar himself took a personal interest in the school, and saw good order observed. The children were always occupied, a definite timetable being allotted and including physical recreation. Ferrar gave the religious instruction himself, sometimes devoting several hours daily to it. On Sunday Ferrar examined the children from neighboring houses. For every psalm which they could say perfectly each child received a psalter and a penny, and his Sunday dinner. Sometimes these were forty or fifty in number. For the adult members of the family morning and evening devotions were prescribed, and social service was done among the country people of the neighborhood. F. W.

**FERRARA, UNIVERSITY OF, ITALY.** — An institution founded in 1391 through the efforts of the Marquis Alberto V of Este, who secured a bull from Pope Boniface IX. Schools had, however, existed in most of the faculties before this date. The bull established a *Studium Generale*. The maintenance of the university fell on the municipality, which found the burden too heavy in 1394, and allowed the university to decline. An effort to revive the institution in 1402 met with no greater success until 1430, when John de Fivotis was invited with his students from Bologna, and at the same time Guarino de Verona lectured at Ferrara. From 1442 on, the university made rapid progress. Ariosto and Savonarola were connected with it. Its reputation in the fifteenth and sixteenth century rested on its medical faculty, although it was also notorious for cheap degrees. At the end of the eighteenth century the long period of decline culminated in the closing of the institution. In 1815 a new university was organized, with four faculties, theology, law, medicine, and mathematics, to which an engineering school was added in 1824. The theological faculty has been dropped. In 1860 the institution became a free university. The municipal authorities of Ferrara are intimately connected with the administration of their local university. The enrollment in 1909-1910

was 409, the majority of students being in the faculty of law.

**FERRER, FRANCISCO Y. GUARDIA** (1869-1909). — Spanish educator, and founder of the Modern School (*q.v.*) at Barcelona. His career will always arouse the interest, and it may be, the passion of mankind. The tragic termination of his life in the trenches of Montjuich (Oct. 13, 1909) left the world outside divided into two hostile camps, — the one composed of those who see in Ferrer the incendiary and the insurrectionist, and the other of those who venerate him as the rationalist educator martyred at the hands of the obscurantists.

The political controversies centering in the personality of Ferrer are necessarily foreign to our immediate purpose. This article will only deal with the part he played as an educational publisher and innovator, and his contribution to pedagogy in the foundation of the *Escuela Moderna*.

The circumstances leading to this epoch-marking event — related by Ferrer himself (see his article in *España Nueva*, June 16, 1906), are unfortunately too long for mention here. Suffice it to say that the realization of his plan of "education based solely on the natural sciences" was made possible by the material resources secured to him by certain dispositions in his favor made in the will, dated Jan. 20, 1901, of a rich pupil of his, Mademoiselle Menier. The original in French is deposited at Milan (Giacomo Galli, Notary, No. 2273). The lady died the same year, and Ferrer thereupon entered in possession of his heritage. This legacy secured him an annual revenue of some 36,000 francs. He raised large sums of money — a total of 450,000 francs — by mortgage on this property, and considerably increased his fortune by successful speculations. The money thus acquired he always treated as an instrument for modifying by dint of education the mental ideas of his countrymen. A system of education on rationalistic lines was the challenge he threw into the camp of clericalism and illiteracy in Spain. (See SPAIN, EDUCATION IX.)

In his early days, Ferrer had been an ardent revolutionist, but, to quote his own language, "When Zorrilla died (1895) I lost all my confidence, which had been already much weakened, in the results of a revolution effected by superficial revolutionaries. . . . From that time forward I devoted all my activity to the task of establishing a school, which, in my humble opinion, might serve as a model for all the schools which advanced bodies were endeavoring to found in order to preserve the child

from the mendacious teaching of the official schools." That was, he adds, "the origin of the Modern School."

Those who best knew Ferrer in those early days confirm the foregoing statement as to his almost fanatical faith in the socially transforming power of education. He believed that the only means of realizing what is good is to teach it by education and propagate it by example. Whether Ferrer's view is sound is an open question, but there can be no doubt that his conduct throughout the last decade and a half of his life was consistent with the doctrine as above set forth. Clearly any other line of policy was dangerous to his cherished ideals, and would have involved the ruin of his fortune, besides wrecking his flourishing business, the stability of a wide network of rationalist schools, and the scholastic future of some 10,000 scholars. (This was the estimated number attending the one hundred schools or thereabouts, at their closure in 1909.) Had he been a vulgar assassin or chief of a revolution, as his enemies declared, he surely would not have hampered his subversive operations with the tedious organization of a network of rationalist schools and the launching of a big series of pedagogic publications. His publishing stock of 115,000 copies of his books was seized by the government when his property was sequestered.

In the eight years from 1901 to 1909, during which there was a thirteen months' interregnum of inactivity, June, 1906–July, 1907, owing to Ferrer's imprisonment awaiting trial at Madrid, the record of Ferrer's publishing output included the issue of forty volumes of educational manuals. These embraced three volumes of *Universal History* (Jacquinet); *Spanish History* (Estevancz); *The First Ages of Humanity* (Professor Engerrand); *Super-organic Evolution* (Professor Lluria; prologue by Ramon y Cajal); a series of six volumes by Dr. Odón de Buén, viz. *Physical Geography* (prefaced by Réclus), *Natural History* (2 vols.), *Mineralogy*, *The Stone Record*, *The Ages of the Earth*; *Ethnic Psychology* (Dr. Charles Letourneau, 4 vols.); three volumes of Spanish and French grammar; two volumes of choice extracts printed in varied types of handwriting, published as graduated school exercises in the reading of script; etc. These books, excellently printed and well bound, were sold at two pesetas each (40 cents) and found a profitable market, not only with the general reading public in Spain, but with the founders, professors, and pupils of the one hundred schools ultimately formed on the plan of the Escuela Moderna. The Supreme Council of Bishops of the Independent (Catholic) Church of the Philippine Islands formally adopted seven of these manuals as textbooks in their seminaries and schools. (See Bishop Aglipay's letter in Ferrer's *Boletín*, June, 1909.)

In addition, he edited a continuous monthly

series (October, 1901, to July, 1909) of educational *Boletines* in which the proceedings of the Escuela Moderna are recorded. The *Boletín* contained articles by men like Letourneau, Anselmo Lorenzo, Zola, Haeckel, Flammarion, Elisée Réclus, Berthelot, Naquet, Kropotkine, Odón de Buén, Ferdinand Buisson, etc. He also issued at Brussels an educational review, *L'École renouée* (monthly, April to November, 1908) principally devoted to the theoretical exposition and discussion of the doctrines of the Escuela Moderna, and of the International League for the Rational Education of Children, of which Ferrer was president, and Professors Haeckel and Sergi, two vice-presidents. The second volume of this review (Paris), issued weekly from Jan. 23 to July, 1909, was almost exclusively occupied with the practical problems of pedagogy.

Ferrer was stricken down when his work was taking new and yet more serious flights of constructive activity. For months prior to his death, he was engaged in launching a new *Encyclopedia of Popular Teaching*, to consist of fifteen volumes, ranging from *The Evolution of Worlds* (Vol. I), the *History of Civilization* (Vol. VIII); the *Evolution of Technics and Art* (Vol. XIII) to *Man and the World* (Vol. XV). He was busy preparing his *éditions de luxe*, illustrated with engravings by the renowned artist, Kupka, of *Man and the Earth* (Réclus), and the *Great Revolution* (Kropotkine). The first announcements of these works appear in his *Boletín*, dated February, 1909, and are continued month by month till the last issue dropped from his hands in the fatal July days. The will, dictated by Ferrer a few hours before his death, charged his testamentary executors (one of whom is the present writer) with the duty of publishing certain of these works, together with five books (amongst them two by F. J. Gould) of the Moral Instruction League (London). These books he had but lately taken home from England, and was studying and annotating them at Barcelona for publication, when the insurrection submerged his labors in the rising tide of clericalist reaction. (See extract from his letter to the present writer, cited by William Archer in *McClure's Magazine*, November, 1910.)

Ferrer's work is for the time being arrested, but the spirit of Ferrer is still alive in his native Spain, and may at any moment embody itself in a revival of the ideas and institutions of the Escuela Moderna. W. H.

**FERRIS, ISAAC** (1798-1873). — College president; graduated at Columbia College in 1816. He was instructor in the Albany Academy; organized the Rutgers Female Institute, and was its first president (1839-1852), and was president of New York University from 1852 to 1870. Author of *Domestic Christian Education* (1835). W. S. M.

**FERRY, JULES FRANÇOIS CAMILLE** (1832-1893). — French statesman. Minister of Public Instruction, 1879-1880; and again in 1882. It was during his incumbency that the great fundamental laws which form the basis of the French system of primary education were passed. Religious instruction was banished from the schools; education was made compulsory between the ages of six and thirteen; and instruction in all grades of the primary (or elementary) schools was made gratuitous. The marvelous educational activity of the time is still further evidenced by the requirement that each department should provide adequate normal training for its elementary teachers; two higher normal schools, one for men and the other for women, were founded to supply the teaching force of the departmental normal schools; and state education for girls became a reality, first by the establishment of a system of lycées and colleges for young women, and secondly by the creation of a higher normal school to train the teachers for these lower schools. In all these great movements Jules Ferry played a leading part.

**FERULE IN EDUCATION.** — See PUNISHMENT, CORPORAL.

**FESTIVALS, SCHOOL.** — It is impossible to draw the line between the more formal type of school celebration and the school festival, understood as implying something of festal gayety and display. For decades, and indeed

it may be said for centuries, schools have had celebrations of the formal type, such as Speech Day, or Prize Day, in the schools of England and the academies of New England, the presentations of Latin plays such as the famous Westminster plays (for which see article on DRAMA AND EDUCATION), the graduation or commencement exercises of public and private schools, Founders' Days, and other commemorative occasions. As a rule these academic exercises have had little of the festal spirit; they have been formal and sober, and scarcely fall under the category of festivals as the term is used here.

It was Ruskin in more recent times who helped more than any one else to enlarge the scope and develop the picturesqueness and festal quality of school commemorations. The May Day celebration, with its return to the old folk ceremony of choosing and crowning the May queen, which he succeeded in getting introduced into some of the schools of England, may serve to mark the adaptation of the old folk festival of the Maying to a school festival; and the fact is indicative of the reason why of late years school festivals of this type have tended to multiply. The old folk celebrations have declined and often faded from memory; and those who have either recalled them or have realized what a valuable element has passed away from our modern civilization, have endeavored to revive them through the school and bring back into the lives of the young, at least, their charming gayety. In New England, for various reasons, festal celebrations have never found much favor. The Puritans left all such fripperies behind them when they crossed in the *Mayflower*. In old England they have never quite died out, more especially in some of the more remote country districts; but that they have ceased to play any general part in the lives of the people and the children in large cities is evidenced by the recent "revivals" of one sort and another, such as the revival of morris dancing, popular games, ballads, and pageants. In former days, when the major festivals of the year were celebrated socially and domestically, their celebration in the schools was unnecessary. Christmas and New Year, Twelfth Night and Candlemas, Valentine's Day, May Day, Michaelmas Day, Harvest Thanksgiving, and Guy Fawkes Day were commonly celebrated by the community, in the social circle and the home; and, in the case of religious festivals, by the church, and more recently by the Sunday school. The occasions were generally observed as school holidays. But times altered. Under the busier industrial order which has changed the ways of Merrie England (not to mention other countries) the folk, now become wage workers, have had little time for holidays and the cultivation of the old folk arts; and so the old revels, the songs and dances, the mummings and the pageantry have gone.

May Day Festival in a Public Park, Buffalo, N.Y.

May Day Festival in Van Cortlandt Park, New York City.

SCHOOL FESTIVALS.

The school festival may, then, be regarded as primarily an attempt to revive in and through the school (or other educational agencies, such as the settlement and playground association) the spirit and the folk art of these old festivals, — so rich in symbolism and ritual. The eagerness with which this may be done is to be measured by one's estimate of the cultural and pedagogical values which reside in such festival celebrations. That the festival may be an instrument of culture need scarcely be argued: one has but to recall the festivals and pageants which were such a vital form of popular art in the Middle Ages. That it is a form of culture sadly needed among us in America is obvious when we think of our ways of celebrating Independence Day (the Fourth of July) and New Year's Eve, for example, which, instead of being mere orgies of noise and feasting, might have some suggestive and poetic quality appropriate to the occasion. As examples of banality certain college commencements attain high rank.

In order that the school festival may be regarded as an important pedagogical instrument, it is necessary to raise it to the dignity of a regular part of the work of the school. Hitherto, the school exercises as those which have been held on occasions like Washington's Birthday, Arbor Day, and Independence Day, have been "extras" which have involved much hard labor on the part of the teachers, and rehearsals out of school hours by the pupils. They have commonly lacked the essential elements of the festival, namely, joy and spontaneity. These elements cannot be secured unless the requisite aptitudes are consistently developed by steady work in declamation, dramatization, singing, and dancing in the classroom, gymnasium, and assembly hall. This means that these subjects are to be recognized as important parts of the school curriculum, and not as mere "fads and frills"; and that the time spent in occasional coordinations of the work done in each for the purpose of festival productions is time well spent, and worthy of being provided for in the time-table. The work of preparation, instead of being a burden and an extra, must be legitimate and leisurely work, justified by reason of the educational values which it yields.

That there are such educational values those who have handled the school festival from this point of view testify abundantly. The evidence to be cited here drawn from the experience and practice of an institution where, for many years, systematic endeavor has been made to develop the festival as an integral part of school work, namely, the Ethical Culture School of New York City. Here the festival has been regarded as a means of preparing the young for life, — not only the life of work, but the life of leisure and recreation. There is a return to the Greek idea of the double function of education, that it shall prepare for refining

leisure as well as for citizenship. The deliberate endeavor to educate for leisure may be justified to-day in view of the increasing difficulty which the worker, the craftsman, or the business man finds in obtaining any generous development, through his minutely subdivided work, and in view of the further fact that the people of to-day have lost the old art of social self-amusement. They are merely passive in the hands of the box office and the caterer. The same is equally true of the children of to-day; they, too, have lost the old arts of childish play and recreation, and must actually be taught to play effectively and wholesomely. The school festival not only teaches the young how to play or recreate themselves through participation in the fine arts of story telling (by mimicry and dramatization), song, dance, ceremonial, — but helps to form and standardize the taste toward the enlightened patronage of the theater and the vaudeville, the concert and opera, and of course the literary expression of these in the printed song, story, and play.

Supplementing these larger social and educational justifications for the festival as a school institution, further pedagogical reasons may be cited. First, the festival properly conducted is the most vital way of coordinating a majority of the subjects studied in the school, — English literature and composition, music, art, dancing, domestic art, shop work, and foreign languages. It is worth while to devote a fortnight or a month every year or every other year to a piece of intensive work in real coordination. Whether the play or pageant represented is composed by the pupils as part of their regular work in English, or whether it consists of some classic or standard play, such, for example, as one of Shakespeare's plays, studied in the high school, the work of the class or classes engaged is work which has not only the normal value of the regular work, but the added value which comes of deepened interest and delight; it is brought to the glowing point, and its effect lasts for years. The music required for the festival is readily incorporated in the regular class work by any cultivated music teacher worthy of his hire. The same is true of the art work involved in the preparation of scenery, stage settings, decorations, and programs needed for the occasion. Only a pedant will be blind to his exceptional opportunity to produce real art. The dances, which must find an important place in any festival, may by a skillful teacher of gymnastics or physical culture be adaptations of work prescribed for the pupils. The costuming will be taken care of in one or more of the sewing and dressmaking classes, if possible by the actors; but if they are too small, a high school group may be asked to function. The stage properties will be provided by the class as a project in shop work. Foreign languages may be involved by the selection occasionally of plays or parts of plays in French and German, or even, for high school

purposes, in Latin and Greek. The problem involved in effecting this coördination of school activities reduces itself to a problem (not an easy one, it may be said) of school organization.

In the second place, the festival is a means of emphasizing and maintaining the right method of dealing with the subject which is central in festival production, that is, English. It emphasizes the fundamental significance of the oral method, and the fact commonly lost sight of, that literature is fundamentally oral and auditory. The principle which should be uppermost in the teaching of literature is that which requires that each species of literature should be treated according to its kind: singable songs should be sung, stories should be quite frequently recited or enacted after the manner of the genuine story teller, and plays should ordinarily be presented dramatically, as they were intended to be by those who wrote them. Thus the festival becomes a means toward that reform in English studies which is being pressed for by the more eager and alert teachers in our schools.

Further reasons may be summarily stated. For each of the subjects involved, festival work is one of the most effective methods of learning by doing; and for the young child it is a legitimate way of satisfying those fundamental dramatic or mimetic instincts which are natural to childhood. Again, it aids the discovery of special aptitudes in the pupils, as these are disclosed under the unusual demands and with that stimulation of the powers which the work involves. Lastly, the festival may be the most powerful means of fixing memorable events and personalities or great ideas in the heart and mind of the child; the drama of the seasons, with their parables of sowing and reaping, of springtime and harvest, of winter sleep and vernal resurrection; or the sacredness of citizenship in one's country and city; or the achievements of the makers of destiny, our heroes, national and local, as well as of the dominating figures of universal history.

The difficulties in the way of organizing festivals with these ends in view are considerable. The prime condition of success is that the various forms of festival activity shall be kept alive as part of the regular work of the school. This means that the children shall be in the habit of singing their songs as the natural daily expression of their innate lyric impulse; that, similarly, they shall be in the habit of giving dramatic expression to ideas and of reproducing the stories which have been told to them by means of gestural and dramatic representation — that being the method proper to children who, lacking words, resort to the more fundamental method of mimicry. This is, after all, little more than a revival of the arts of childhood which in the past have been the child's most precious legacy; the great formative arts of play, — the songs and games, the dance drama and balladry of the children of the ages.

The true literary nature of the child is revealed in these, and the educator ought to take his cue from them.

If, then, throughout the grades of the elementary school the children sing and dramatize, as they should, they are always in a condition to be called upon to produce at short notice any play or part of a pageant which may be arranged for by the teachers and faculty. They will act and sing naturally and spontaneously, with no touch of that staginess which so many people fear will be the result of dramatic work. There will be a constant supply of small recitals and plays, for school and class assemblies; the fruits of regular work in literature, music, etc. A second condition of effective organization of festivals is that they shall be put into the hands of the classes or groups of classes in rotation, the particular festival, — for example, that of Washington's Birthday or Patriot's Day, — being assigned to those classes which are engaged in the study of material that lends itself to such a festival. The school as a whole will share in the festal spirit through the songs which are to punctuate the presentation.

Effective organization further implies that the plan of festivals for the year shall be agreed upon in advance by the school authorities, and that a festival committee composed of heads of departments shall be charged with the execution of the plans. The festivals may vary from year to year as to their number and the emphasis to be placed upon each. The greater festivals, such as Thanksgiving, Christmas, Washington's and Lincoln's Birthdays, which may be combined in a Patriot's Day festival, the spring or May Day festival, and the graduation festival, may be supplemented by many minor celebrations and commemorations according to the number of red-letter days in the calendar of the locality. There may be a City Day, which should be devoted, as is altogether too infrequently done, to the glorification of one's city or state. There may be a Shakespeare festival in April, a Founder's Day, or, where there are large groups of the different nationalities, a St. Patrick's or St. David's or St. George's festival. These minor festivals may take the place of an ordinary school assembly.

The material to be utilized may vary considerably. It may be the pupils' own dramatization of history material, such as the first Thanksgiving, with appropriate introduction of Indian life. It may be the dramatization of a story or an eventful career, such as *The Man Without a Country*, for Patriot's Day, or the story of Lincoln's life and times. It may be an original play worked out by the class to illustrate the central idea, including original songs (new words for old tunes) such as Christmas carols, many of which can no longer be used unaltered in a mixed community with a large Jewish element. Or the class may present

some classic play, Shakespeare's *As You Like It*, or *A Midsummer Night's Dream*, for a spring festival; or a play in the classic manner, such as Robert Bridge's *Demeter*, for the Thanksgiving or harvest festival. Simple and worthy plays for children have so multiplied of recent years that there is now a considerable repertoire upon which schools may draw.

Perhaps the most easily handled festival is the type which may readily be given on May Day or at Christmas, in which a number of classes collaborate, each contributing to a varied program some one scene which will fit into a general scheme. Thus the May Day or spring festival may reproduce the varied features of the old English May Day celebration. One class may contribute the ceremony of the choosing and crowning of the May queen. Another class may contribute a band of Sherwood foresters, and enact episodes from the life of Robin Hood, such as those narrated in the Robin Hood ballads. Another class may form a group of peasants who dance the old morris or country dances for the entertainment of the queen; another, a group of maypole dancers. So, too, at Christmas there may be a composite of classes, each of which may reproduce some scene or some detachable fragment of a play which it has produced during the year, or an interpretative dance, or a fairy-story pantomime after the manner of the old English Christmas pantomime. In this way five classes of, say, one hundred and fifty children may present a charming pageant, marching into the hall with banners and insignia, singing each its appropriate song and contributing each in turn its item of a well-coördinated program.

The results to be accomplished by such development of the school festival may be briefly summarized as the development of the coöperative spirit and of team work among the classes, the discovery of aptitudes which are not evoked by the ordinary kind of class work, the preservation of dramatic naturalness and spontaneity on the part of children, the proper oral and dramatic treatment of literature, the quickening of the spirit of joy and refined delight, the education of children in the appreciation of simple and chaste amusement, the development of clear and pleasant speaking and of good manners, and, finally, the stocking of the children with a body of song and poetry which they will probably never forget. Here a final word should be said as to the connection to be made between the development of the festival in the school and the development of the festal spirit in the home and the community. In a school in which the festival performances are regular, the children learn ways of refining self-amusement which they can carry into the home. They have songs to sing and games to play, and a ritual or ceremonial appropriate to the great festival occasions, which may have the effect of actually transforming the life of the home on such occasions. Their picnics and

excursions, their vacation activities, may also be enriched in the same way. Thus it is that to work for the development of the festival in the school is to work for better ways of social recreation and for the revivification of the folk festival as a form of popular culture and entertainment.

**The Recent Development of the Festival.**— Many diverse and seemingly unrelated tendencies have led to the recent revival of the festival and the pageant in schools and colleges and outside of them. The quickened interest in folk art—folk song and story, folk balladry and dance, folk drama and folk festival—is one of these. Another closely allied tendency finds expression in the efforts of such organizations as the Ben Greet Players toward the revival of early drama, notably the miracle and mystery plays, under the simple conditions of the early English life which produced them, and the rendition of Shakespearean plays in the spirit of the Elizabethan epoch and without the paraphernalia of the modern theater. This tendency naturally connects itself with actual survivals of the old folk drama such as the Oberammergau Passion Play. To the same historic interest we may ascribe the numerous pageants on the occasion of important historic commemorations, the centennials of towns and cities, such, for example, as the great Warwick pageant, which was a genuine folk undertaking, involving the coöperative industry of the people of all classes in that little city on the Avon. The example thus set in England was followed here in historical pageants at Quebec, Champlain, Deerfield, Gloucester, and elsewhere. Yet another form of expressing the impulses of picturesque festival presentation is to be found in the development of the dance and play festival, in which some of the leading settlements and the recently formed playground associations have taken the initiative.

Returning to the first of these influences, it may be noted that there has been an ever-increasing number of presentations by universities, colleges, and schools of ancient dramas and Elizabethan plays, either for their own sake or as part of some larger festival. From a list of such presentations (see the *Chicago Dial* of Aug. 1, 1907) may be mentioned the production at Brown University of Marlowe's *Dr. Faustus*, and of *Ralph Roister Doister* at Tufts College in 1905; Harvard's production of Ben Jonson's *Silent Woman* in the same year, and Dekker's *Shoemaker's Holiday* in 1889; Tufts College's presentation of the *First Pageant of the Shepherds* in 1900, and Yale's production of the *Second Pageant* a little later. The University of Vermont, the Roxbury, Mass., High School, Butler College, Indiana, the University of Chicago, Wellesley College, likewise appear in the list. Bryn Mawr College must be mentioned here as representing another development of the festival idea in its now famous May Day revels, in which all the elements of the old English folk festival—

singing, dancing, mumming, ritual — are incorporated. (See DRAMA AND EDUCATION.)

Again, presentations of Greek plays have become more numerous, and have led to the erection of Greek theaters, such as the beautiful example at the University of California. Opportunities have also been provided for these and other forms of dramatic presentation by the erection of halls with suitable stage accommodations, and of large stadia for athletic displays, Olympic games, and miscellaneous festivals, such as those provided at Harvard and Tacoma.

The schools, too, have been developing new types of school festivals and improving such occasions as commencement by introducing, in the form of processions, ceremonies, and dramatic scenes, elements that for the first time have given a genuine festal spirit to these occasions. The training schools must also be included. The Boston Normal School celebrated the opening of its new buildings by giving a great Pageant of Education; the Brooklyn Training School for Teachers attempted something of the same sort, and Teachers College, New York, produced old English carolings and Christmas rites.

Finally must be instanced the dance festivals which have been given in the public parks in Chicago, New York, Pittsburg, and elsewhere, and have consisted of national dances contributed by people of different nationalities in our great cities. To these have been added dramatic presentations; thus on one of the Boston playgrounds the Greek myth of Prometheus was presented in pantomime and dance. The settlements have also given, either in small parks or in the closed street, little plays or pantomimes, such, for example, as the Robin Hood play, or mask, given by the Greenwich House in Jones Street, New York, the street being closed to traffic for the purpose.

This rapid survey would be incomplete without a reference to the many important attempts, in which children have for the most part participated, to transform the senseless and noisy celebration of the Fourth of July (Independence Day) into an occasion of interesting and picturesque commemoration, — "a safe and sane Fourth," as it has been styled. In Springfield, Mass., in particular, a great step forward has been taken in the direction of substituting, for the individual celebration of the occasion by the discharge of the fire-cracker, processions with floats representing historic episodes and personages, athletic contests, dances, etc. With Springfield, such cities as St. Paul and Pittsburg should be mentioned as leaders in this laudable enterprise. In some schools and localities a similar transformation of Hallowe'en, with its mischief, its destructive amusement, and its accidents, has been attempted.

We must not overlook the stream of tendency in this direction that has flowed steadily from

the kindergarten. In many a school where there is no other form of festival, there is always something in the nature of pantomime and merry-making around the tree in the kindergarten. The theorists who have learned of Froebel and Pestalozzi have not been slow to seize upon the exemplification which the festival and all forms of dramatic work in the schools have made of the neglected motor element in the education of the young. It is now common in textbooks of pedagogy to find a plea made for the development of the dramatic instincts of the child as involving the most vital form of learning by doing. Teachers of the primary grades have come to see that the child's natural way of reproducing a story or illustrating an idea is not so much by word as by dramatic imitation. Hence the growing tendency to dramatize not only the reading lesson, but the history and the geography work of the class. The most striking outcome of this tendency is perhaps the quick multiplication of late of dramatic readers of all kinds, and of little collections of plays for children of all grades in the primary and grammar schools. That such work vivifies the child's interest in his studies has been abundantly demonstrated. That it impresses the mind as nothing else does is also clear. If further justification of the dramatic idea and method were needed, it might be found in the interesting history of the short-lived children's theater, conducted by Miss Herts at the Educational Alliance in New York City, the effect of which was to generate an unprecedented demand in the local libraries for the works of Shakespeare, Mrs. Burnett, Mark Twain, and others from which the material to be presented by the young players was drawn.

There can be little doubt that this recently developed attention to the importance of the dramatic element in education and recreation is no passing fad. The festival must win its way as an educational instrument. But the working out of festival undertakings must go forward steadily before any sustained effort can be made on a large scale by school children or groups of schools. An opportunity for the participation of school children in the great popular festival was offered at the time of the Hudson-Fulton celebration in New York City; but, with the exception of one or two groups of the public school children, the idea failed of fulfillment. Elaborate plans were carefully made by experts; but the politicians laid grasping hands upon them. Many possibilities are suggested by the pathetic May parties held every spring by groups of children from the poorer districts of New York in Central Park of that city. These await a transforming hand. Because it is a natural historic form of childish amusement and culture, which has found its place among the children during the long centuries of the past, the festival, as a combination of singing and dancing, marching and

play-acting, will surely continue to grow in favor with educators, with the public and parents, and, above all, with children themselves.

**FIBONACCI, LEONARDO, or LEONARDO OF PISA** (c. 1175-c. 1250). — The best of the mediæval mathematicians of Europe. He was born at Pisa during the period of that city's great commercial supremacy.

As a child Leonardo was taken by his father to Bugia, the modern Bougie and the Salde of the Romans, on the Algerian coast, and put to school under a learned Moor. As a consular agent of some kind, the father was in touch with the commerce of Pisa; and it was probably on this account that Leonardo was able to make his voyages about the Mediterranean. He visited Egypt, Syria, Greece, Sicily, and Provence, and became acquainted with the various arithmetical systems in use. All of these systems, he tells us, he counted as error compared with the Hindu arithmetic (*Quasi errorem computari respectu modi Indorum*). He therefore composed an extensive treatise upon this subject, the *Liber Abaci*, which appeared in 1202. His revision of 1228 is extant, but no copy of the first manuscript is known. By this work Leonardo did much to make the Hindu-Arabic numerals (see NOTATION) known in Europe. He also wrote a work entitled *Liber quadratorum*, in which there is a considerable treatment of indeterminate equations; another entitled *Practica geometriae*, which includes some trigonometry; and one bearing the name of *Flos*, and treating of equations. He was evidently in touch with the learned men of his day, for he dedicates one of his works to his teacher, Michael Scot (*Scriptistis mihi, domine mi, magister Michael Scotti, summe philosophæ, ut librum de numero, quem dudum composui, vobis transcriberem*). A statue of Leonardo may be seen in the Campo Santo at Pisa. His works were published by Prince Boncompagni under the title *Tre scritti inediti di Leonardo Pisano* (Florence, 1854; second edition, 1857), and *Scritti di Leonardo Pisano* (Rome, 1857). D. E. S.

**FICHTE, JOHANN GOTTLIEB** (1762-1814). — The German philosopher; born in Rammenau, Upper Lusatia, May 19, 1762. He studied at the University of Jena, and then gained a precarious livelihood for several years by tutoring and by writing for magazines. At first he was a follower of Spinoza; but later his study of Kant revolutionized his philosophical thinking. In 1792 appeared his first book, *The Critique of All Revelation*. Published anonymously (through a mistake), it was hailed by the critics as a work of Kant himself; and when the authorship was announced, Fichte became famous. In 1794 he went to Jena as

professor of philosophy, and at once became very popular. Four years later he severed his connection with the university, because of difficulties which grew out of the charge that his teachings were atheistic. For a short time he gave lectures on philosophy at the University of Erlangen, and later at Königsberg. When the University of Berlin was founded, he was one of its foremost professors, and he served as its second rector. He died in Berlin, Jan. 27, 1814. His chief works are *The Foundation of the Whole Science of Knowledge* (the *Wissenschaftslehre* of 1794), *The Foundation of Natural Rights*, *The Science of Morals*, *The Vocation of Man*, *The Way to the Blessed Life*, *Characteristics of the Present Age*, *Addresses to the German Nation*, and *The Facts of Consciousness*. His *Complete Works* appeared in eleven volumes (1834-1835 and 1845-1846), edited by his son, who also published his *Life and Literary Correspondence*.

The fundamental conception in Fichte's philosophy is that of the ideal. Man's life is a constant striving to realize the ideal of unity. The search for knowledge is an effort to make ourselves one with the object of knowledge. The life of the practical man is an attempt to bring an external object or another will into harmony with his own will. The artist is continually striving to make the sensuous material the vehicle for the expression of his artistic purposes. And the moral and spiritual life is the effort to bring into harmony the various conflicting impulses within the self. And just as the ideal of unity is the fundamental thing in our lives, so it is the deepest thing in the universe. The history of the world is, essentially, nothing but the process in which the ideal is gradually realizing itself. This self-realizing ideal or idea is what Fichte means by "God." He conceives of God, not as a personal consciousness, distinct from the world, but as the spiritual power whose self-expression *is* the world. The ideal is not a mere something which we fashion in imagination and then strive to make actual. On the contrary, it lives and strives in each one of us; it has fashioned us to be the vehicles of its self-expression. The world, then, is the life of God. God has no distinct consciousness apart from ours; he comes to self-consciousness in us. The more perfectly the ideal is realized in men, the more completely does God exist.

Fichte's idealistic theory of matter follows naturally from the principles just laid down. The material world is not something fundamentally unlike spirit. The history of the world is the effort of the idea to become fully conscious of itself and fully at one with itself. Now all that we call "consciousness" involves an element of opposition. The child becomes aware of himself in opposition to, and in distinction from, other things. Thus we cannot get a consciousness of self without a consciousness of a not-self, an external object. But the

external object is not, as we naively suppose, utterly unlike our own mental life. Everything that you can say of it is in terms of consciousness. It is hard, round, red — what are these adjectives but names for certain experiences which you and others have? All reality, then, is conscious experience. The "external object" is simply the way in which we interpret an opposition in consciousness that we are striving to overcome. And just as conflict with material things is a means to the attainment of a richer consciousness, so conflict with other wills and final coming into harmony with them serves to deepen and enlarge our experience. This is why the ideal, which is ever struggling toward fuller self-realization, manifests itself in many individuals instead of one alone.

Human society should steadily progress toward perfect harmony of all men with one another, and toward complete mastery over the forces of nature. For this purpose it needs a clear understanding of the goal, of the degree of attainment, and of the means by which further progress may be made. It needs also wise men to guide its progress. There are two classes of scholars — the teacher and the pragmatic scholar. The function of the former is to give to his generation the understanding necessary for its progress and to train new scholars; that of the latter is to use the knowledge which he has attained in directly promoting social progress, *e.g.* in modeling legislation or in subduing the forces of nature. All those who have the direct guidance of human affairs should be scholars. Mere learning cannot make a scholar; the true scholar is one in whom the Divine Idea is a living power. All teachers, even in the lower schools, should be scholars, though not necessarily "finished scholars"; *i.e.* they should be filled with the love of knowledge and should be continually striving to enlarge their knowledge.

This conception of the function of the teacher is unfolded chiefly in *The Vocation of the Scholar* and *The Nature of the Scholar*. These two works and *The Addresses to the German Nation* contain Fichte's most important utterances on the subject of education. When Germany was prostrate at the feet of Napoleon, Fichte was one of the first to point out that her only hope lay in a complete reform of her educational system. In the powerful *Addresses to the German Nation*, delivered in Berlin in the year 1807-1808, he urged a thorough reorganization of the German school system along the lines indicated by Pestalozzi. While he criticized it in some respects, he believed that the Pestalozzian doctrine is in its essence correct. And his championship of it had much to do with the introduction of the new method into the Prussian schools. The chief suggestions of educational theory in the *Addresses* are the following. All real progress comes from the people; hence the whole people

should be educated. Education is the function of the State. The children should be separated from their parents during the entire period of their training, at least until we have a generation of parents who have been brought up under the new methods. The two sexes should be educated together, and to a considerable degree should have the same education. All children should be trained to work with their hands; but Pestalozzi's suggestion that they do this work while they are studying is ill-advised. In the manual training, emphasis should be put upon agriculture, the care of animals, the mechanic arts, — in short, upon those occupations which the majority of the pupils must pursue in later life. Physical training should form part of the regular instruction; the methods should be devised by men who have a thorough knowledge of anatomy and also of psychological principles. In the mental training the chief aim should be, not to impart knowledge, but to develop mental activity and to arouse in the child the love of knowledge and the love for his fellow men. The ultimate end of all education is to develop a pure morality and the spirit of true religion. As to methods of mental training, some of Pestalozzi's theories are open to criticism. We should begin, he says, by giving the child a knowledge of its own body. Here he is wrong; education should begin by teaching the child to discriminate his various sensations. Another error that Pestalozzi makes is that he greatly overestimates the value of reading and writing, and would have the child acquire them very early. He falls into this mistake because his chief concern is to fit the children of the poor to earn their daily bread as quickly as possible. But the errors in his theory are only superficial; its fundamental principles are sound.

**FICINO, MARSILIO** (1433-1499). — Italian humanist; born at Figline, the son of the physician of Cosmo de' Medici, who took the boy under his patronage and destined him to become the translator of Plato into Latin. The lifework of Ficino was devoted to a study of Plato, Plotinus, and other Neoplatonists, and to an attempt to reconcile Platonic philosophy with Christianity. Ficino took orders at the age of forty; and four years later completed his translation of Plato's works, which

were published at the expense of a patron in 1482. He also translated Plotinus, Iamblicus, and Proclus, wrote a life of Plato, and a treatise on the *Platonic Doctrine of Immortality*, a collection of the theories discussed by the Platonic Academy, established by the Medici, of which Ficino was the president.

**FICKLIN, JOSEPH** (1833-1887). — Text-book author and college professor; was graduated from the Masonic College at Lexington, Mo., 1854. He was principal of the high school at Trenton, Mo. (1854-1859); instructor of mathematics in the female college at Bloomington, Ill. (1860-1864), and professor in the University of Missouri (1865-1887). Author of a half dozen mathematical textbooks.

W. S. M.

**FIELD EXCURSIONS.** — See EXCURSIONS, SCHOOL.

**FIELD LESSON.** — In many of the natural sciences, laboratory experimentation and textbook instruction are supplemented by class expeditions into the country, where natural phenomena are observed in their usual setting, and specimen materials are collected. In the high school field work is given in connection with botany, zoology, and geology; in the elementary school with geography and nature study. The field lesson is one type of school excursion. Field lessons and school excursions are valuable and necessary, if the more or less artificial objective work of the classroom is to be properly supplemented. They afford a concrete basis for appreciating much that the school can only give through description. Their use is enlarging in the modern school. They are still largely maintained as voluntary activities outside of regular school hours, though the growing sanction for school excursions during regular class periods tends to extend to class field lessons in the natural sciences.

H. S.

See EXCURSIONS, SCHOOL; OBJECT TEACHING.

**FIELD OF CONSCIOUSNESS.** — Certain experiments indicate that there is a limit to the number of experiences which can be included in a single act of conscious apprehension. There is a still further limitation upon the number of experiences which can be recognized with all clearness. The term "field of consciousness" has been employed to describe the total range of experiences which can be had in a single pulse of consciousness, whether these experiences are clear or vague. The field of attention, on the other hand, falls within the field of consciousness, and includes only those processes which are distinctly recognized.

C. H. J.

**FIELD OF REGARD.** — The totality of outer space which can be seen by the moving eye. It may be represented by a plane surface which moves with the head or the eye, and in which, for any given position, there is a fixated point, — one imaged on the fovea of the eye. It is apparent that resting objects change their positions in the field of regard when the head or eye is moved. R. P. A.

 SANFORD, E. C. *Course in Experimental Psychol.*, No. 119. (Boston, 1894.)

**FIELD OF VISION.** — The totality of points in outer space visible to the immovable eye, sometimes used interchangeably with *field of regard*, which, however, applies properly only to the totality of points visible to the moving eye. The extent of the field of vision may be found by using a perimeter, usually a metallic arc of 90°, at the center of which the eye is placed and made to fixate (see **FIXATION**) one end of the arc. The experimenter determines those points on the arc at which the subject just begins or ceases to see a small object moved along the arc. By rotating the perimeter so as to cover the various meridians of the eye, the entire field of vision may be plotted. R. P. A.

**FIELDEN, SARAH** (1819-1910). — An Englishwoman born in Liverpool, who devoted the whole of her life to the advancement of education. Her grandfather, a Unitarian minister, founded the first undenominational elementary school in Liverpool. Mrs. Fielden showed an early interest in the social and philanthropic work in which the members of her family were engaged. On moving, after her marriage to a wealthy Lancashire manufacturer, to Todmorden, she taught in the factory schools (*q.v.*) of the district for a time, and then in an elementary school which enjoyed government aid. Later she built a model school on her estate at Centre Vale in Todmorden, where she was able to put her own ideas, based on observation of English and Continental systems, into practice, and also to train many teachers. When the school boards were established, she became a member of the Todmorden School Board from 1874 to 1889. During the early part of this period she lectured locally on *Methods of Teaching*, with practical illustrations in a class of selected pupils. In her school she introduced a system of signals to maintain discipline and order. She gave useful evidence before the Royal Commission of 1888. In 1902 she was co-opted a member of the local education committee, a

high tribute to her services to education. Fruitful as her own immediate work had been, the endowments by her of a Chair of Education at the Manchester University in 1899, now filled by Prof. J. J. Findlay, and her support of the Fielden Demonstration School, which through her generosity is now located in a suitable building standing in its own grounds, are likely to lead to results of great importance and influence in English education. The university recognized her lifelong services to education by conferring on her the degree of Litt.D. in 1906.

**Reference : —**

FINDLAY, J. J. *Demonstration Schools Record*. (Manchester, 1908.)

**FIGURATE NUMBERS.** — This term was applied by Nicomachus (*q.v.*) to certain numbers that represented various regular polygons. (See **POLYGONAL NUMBERS.**) The term is now generally applied to the numbers below the line in the following table :—

	1	1	1	1	1	...
	1	2	3	4	5	...
I	1	3	6	10	15	...
II	1	4	10	20	35	...
III	1	5	15	35	70	...
IV	1	6	21	56	126	...
.	.	.	.	.	.	.
.	.	.	.	.	.	.
.	.	.	.	.	.	.

It will be noticed that each number is the sum of the numbers in the preceding row. Thus, 56=35+15+5+1. It will also be noticed that by drawing a diagonal from the *n*th 1 at the left to the *n*th 1 at the top, the binomial coefficients are found. (See **PASCAL'S TRIANGLE.**) These numbers include not only the polygonal numbers (*q.v.*), as indeed all natural numbers, but many that are not polygonal. The subject played an important part in medieval education, but it has now only an historic interest. D. E. S.

**FIGURES.** — See **NOTATION ; SIGNIFICANT FIGURES.**

**FILELFO, FRANCESCO** (1398-1481). — One of the most prominent among the humanists of the Italian Renaissance; born at Tolentino. After studying under Barzizza, he became professor at Padua at the age of eighteen, and in the following year was invited to Venice to teach eloquence and moral philosophy. From 1420 to 1427 he was secretary to the Venetian consul at Constantinople, where he seized the opportunity to learn Greek from John Chrysoloras, a nephew of Manuel, whose daughter he married. On his return to Italy he held appointments as professor of eloquence at Venice, Bologna, and Florence. His reputation as a scholar was very high; his knowledge of Greek, and the possession of valuable

works, which he had brought back from the East, gave him a position of eminence. But he lacked critical judgment, taste, and creative ability, and his personal character was of the worst. At Florence he gave four lectures a day, to audiences consisting of the noblest citizens, on Greek and Latin authors; he also delivered public lectures on Dante. When he quarreled with the Medici, he left Florence, and after a short interval found a welcome in Milan, where he was received by the Duke as a noble. At Milan, with short interruptions, during which he held an appointment at Rome and again at Florence, he remained till shortly before his death.

Filelfo was very productive as a writer; he translated many Greek works into Latin, including selections from Xenophon, Lysias, Aristotle, and Plutarch; his original works were labored and stilted satires and odes, orations and begging letters addressed to men of eminence whenever, through his own extravagance, he considered that his high position as the first scholar of his day was not sufficiently rewarded. Although his influence for the progress of scholarship was considerable, Filelfo presents a character that is the least pleasing among Italian humanists.

**FINGER RECKONING.**—Chiefly owing to the difficulty of obtaining inexpensive material for writing, there arose in ancient times a digital system of representing numbers and computing. It may be compared as to general appearance with the digital language of the deaf and dumb as used at present. Very likely it was a development of the primitive system of

counting on the fingers, which gave rise to our decimal system. (See NOTATION.) At any rate, we have evidence that the ancients used it for the purpose of remembering the numbers in a computation, as on the abacus (*q.v.*), and for the computation itself, and also for the purpose of bargaining. Even as late as the sixteenth century, it was used in Europe for all three of these purposes. It is probable that Solomon refers to it when he says that "length of days is in her right hand," the right hand being used in all such systems to represent hundreds. Possibly Aristophanes (*q.v.*) refers to it in the *Wasps*, when Bdelycleon tells his father to do an easy problem by the help of his fingers. The semi-mythical Numa Pompilius is said by Pliny and Macrobius to have erected a statue of Janus, the fingers of which indicated the number of days of the year. There are several well-defined references to the system in the works of classical writers. Thus Plautus says:—

. . . lævo in femore habet lævam,  
 Dextera digitis rationem computat, feriens femur  
 Dexterum.

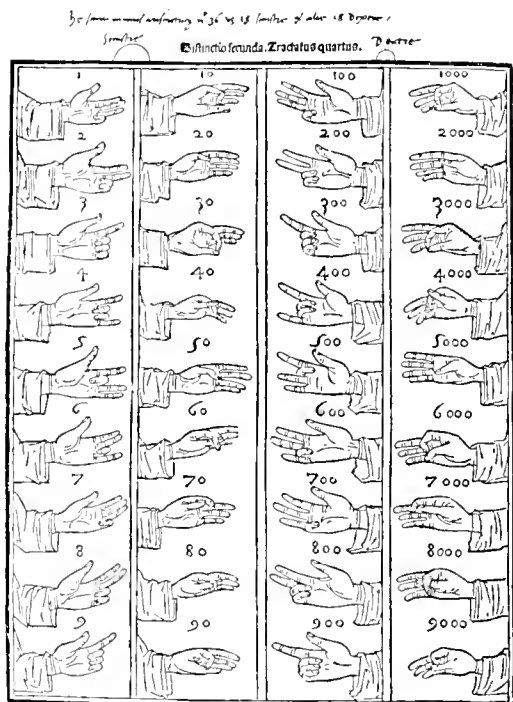

Seneca also speaks of it in these words: *Numerare docet me arithmetica et avaritiæ commodare digitos*, and Pliny uses the expression *Agitas digitos, computas nihil*. The best classical reference is in Quintilian (I, 10, 35), and the first instance of an actual problem is in the *Apologia* of Apuleius. Augustine frequently refers to it in his efforts to inject a Pythagorean mysticism of numbers into his theology. In one of his sermons, in speaking of the "ninety and nine," he says: *Quid est, ad nonaginta novem pertinent? In sinistra sunt, non in dextera . . . unum addit, ad dexteram transitur*. This shows that the people to whom he was speaking must have been familiar with the fact that 99 was represented on the left hand, and 100 on the right.

It is to Bede (*c.* 725) that we are indebted for such detailed knowledge as we have of the medieval system. (*De loquela per gestum digitorum*, in his *Opera omnia*, tomus I, p. 689. Paris, 1862.) After his time numerous writers are found who give descriptions of the process, particularly in regard to computations for Easter. (See COMPUTUS.) The first good description in print is that of Paciolo (*q.v.*), whose *Summa (Sūma)* appeared in 1494. The system as given by him can be somewhat understood from the following illustration from his work.

Similar illustrations are given in works by Tagliente, Apianus, and Robert Recorde. (For the illustrations see Smith, D. E., *Rara Arithmetica*. Boston, 1907.)

The system continued in use until about 1600, when it died out as a school study, although it has remained to the present time as a tradition among the people. It is not uncommon to find people to-day, particularly in rural communities and in some remote places

in Europe, who multiply on the fingers exactly as the ancients did. Thus to multiply 7 by 8, raise 2 fingers on one hand and 3 on the other (since  $5 + 2 = 7$ , and  $5 + 3 = 8$ ). Then add the raised fingers ( $2 + 3 = 5$ ) and multiply the others ( $2 \times 3 = 6$ ), and the result is 5 tens + 6, or 56. Similarly,  $8 \times 9$  is  $(3 + 4)$  tens and  $2 \times 1$  units.

In practical education at the present time many teachers fear the effect of letting children count on their fingers. It is, however, a race habit, and the danger is easily overcome by continued rapid oral work throughout the early years of arithmetic. D. E. S.

**FINLAND, EDUCATION IN.** — The Grand duchy of Finland covers an area of 144,225 square miles in the northwestern part of Russia, bordering on Sweden and the Gulf of Bothnia. Its population is remarkably homogeneous, Finns forming about 86.7 per cent and Swedes 12.7 per cent of the nearly 3,000,000 inhabitants. The capital is Helsingfors, having a population of 130,844. Abo, the next city in size, has 46,637, and there are six remaining cities with populations of fifteen thousand and upwards. The rural population comprises 86 per cent of the total; and consequently provision for primary education outside of the towns is a matter of supreme concern to the State.

Three influences have determined the course of public instruction in Finland, its relation

to Sweden, with which it was united from the fourteenth to the nineteenth century; the reformed religion; and the diffused sense of national solidarity. Fully 90 per cent of the people are adherents of the Lutheran Church, and five centuries of unswerving devotion to its doctrines and discipline have developed among them a deep sense of moral responsibility, while the exercise of the franchise, which, beginning in the seventeenth century with well-defined class distinctions, was recently placed on a popular basis, has developed equally the patriotic spirit.

**Primary Education.** — There are practically two systems of education in Finland, one clerical, the other national. The former arose from the church requirement that the clergy should examine all children of their respective parishes at least once a year in reading and the Catechism. By the ecclesiastical code of 1686 this elementary knowledge was made a prerequisite to communion, and later codes, in particular that of 1869, have made it obligatory upon the communes to provide such elementary instruction for children whose parents are unable to do so. The annual examination by the parish pastor is a regular fête day for children and adults, and its importance is increased by the fact that every five years reports of the examinations are forwarded to the central Board of Education. The ambulatory schools grew out of this obligatory clerical instruction. In accordance with the ecclesiastical code, every parish is divided into school circles, or districts, varying in number, and a teacher is appointed for each circle. The teacher makes the tour of the circle in a scholastic year, remaining in each of the assigned villages from four to eight weeks, teaching the children of the neighboring hamlets, and then passing on to the next village.

Early in the nineteenth century a movement for national education was started by leading men in the province, and gained the support of the Emperor Alexander III. The chief promoter of the movement was Uno Cygnaeus, who was an ardent advocate of the democratic ideas then rife in Europe. Having been appointed inspector of elementary schools, Cygnaeus made an extended tour for the purpose of studying the systems and principles of popular education in Germany, France, and Switzerland. His practical work in his own country began with the establishment of a normal school at Jyväskylä in 1863, on the model of those in Switzerland. It was a residential school conducted on Pestalozzian principles, the time of the students being divided between studies, domestic industries, and work in the garden and field. The school departed from the Swiss models by the admission of both sexes, although they were instructed in separate sections.

The foundation of the primary school system was laid by the ordinance of 1866, which re-

quired every urban commune to establish a sufficient number of primary schools for the accommodation of all children between eight and fourteen years of age, and to offer a prescribed program of studies. These schools were to be supported by the communes with aid from the state treasury and to be under public inspection. As regards rural districts, the ordinance of 1866 simply provided that the ambulatory schools should be recognized so far as they were preparatory to the primary schools proper. For this purpose it was required that, in addition to reading and religious instruction, the pupils should be taught the elements of writing, arithmetic, and singing. By an ordinance of Nov. 24, 1869, the general administration of the national system of primary education, as well as that of the secondary schools which heretofore had been under ecclesiastical direction, was vested in a central board or council of education, *Oferstyrelsen för Skolväsendet*. The members of this council are appointed by the Senate (constituted by imperial appointment), upon the nomination of the Diet (legislative assembly). The executive chief of the system, the Director-General, is also appointed by the Senate. An assistant director has charge of primary education, and there are government inspectors for both secondary and primary schools.

The establishment and direct control of primary schools rest with local boards or committees; on which the clergy are always represented; the organization and programs of the schools are determined by regulations emanating from the central board. The urban schools are: (1) elementary primary schools for children seven to nine years of age; (2) ordinary primary schools for children nine to thirteen; (3) complementary or continuation schools with a one-year course. There are also preparatory schools with a course of two years for children who have reached the age of ten years and have not learned to read; auxiliary schools for feeble-minded children; and evening schools for pupils above twelve years of age who are unable to attend day schools.

The elementary primary schools are mixed as regards sex; when the higher primaries are reached, boys and girls attend separate schools. The course of study for the elementary schools includes religion (supervised by the clergy), reading, writing, the mother tongue, arithmetic, geometric figures, drawing, singing, and gymnastics; to these branches are added, in the upper section, history, geography, the measurement of surfaces and volumes, the natural sciences, and manual training.

It was not until 1898 that the rural communes were required by law (May 24) to establish public primary schools. The rural school districts must be so arranged that a school may be placed within five kilometers of every family. Even before the passage of this law, nearly every rural district had established at

least one primary school. The rural primary schools correspond in a sense to the upper section of the city schools. They are termed *högre folkskolor*, as children enter them at nine years of age after completing the elementary stage, by means either of the ambulatory school or an infant school. Boys and girls are instructed together in the rural primaries. The program is modeled, so far as possible, upon that for the urban schools. The primary schools are not free, but the fees are small, and may be, and often are, remitted. After the elementary stage is passed, school attendance is not compulsory. Evening schools are maintained for both boys and girls above twelve years of age, who are unable to continue attendance upon day schools. Classes for adults are maintained both in cities and in rural districts, and, if they follow the official course, they receive a subvention from the State.

*The Teachers.*—The law requires that all teachers of primary schools shall be trained, and the first normal school established by Uno Cygnæus has been followed by others, situated at convenient centers. But as primary schools multiply in the rural districts it is not always possible to secure trained teachers for them. Teachers' conferences are conducted by the district inspectors, at which principles and methods of primary education are expounded and the professional spirit is stimulated among the teachers by their participation in the general meeting called by the central director, every three years, for the discussion of programs and methods.

Teachers' salaries vary greatly. The maximum is reached in Helsingfors, where the director, or master, of a school receives 3900 marks a year (\$750) and a directress 3300 marks (\$637). In the smaller cities the annual salary does not exceed that paid in rural schools. The State guarantees a minimum salary with increments of one tenth at stated intervals. After thirty years' service, a teacher is entitled to a pension, amounting to 1000 marks a year for a man and to 750 marks for a woman.

*Statistics.*—The distribution of pupils and teachers among the various classes of primary schools in 1909 was as follows:—

CLASSES	NUMBER	TEACHERS			ENROLLMENT		
		Men	Women	Total	Boys	Girls	Total
Rural schools:							
Infant	1583						38,479
Higher primary	2663	1681	1516	3197	58,989	53,373	112,362
Urban primary schools		311	851	1162	16,770	16,836	33,606
Evening schools					361	371	732
Other primary					249	654	903
Total					76,369	71,234	146,082

If to the total number of pupils given above, namely, 186,082, is added the number of children taught in ambulatory schools, at present estimated at 150,000 (the official report of 1906 gave the number as 183,000) the resulting total, 336,082, is equivalent to 11 per cent of the population.

NORMAL SCHOOLS, 1908

B. Swedish						
Ekenas . . . . .	4	4	8	—	90	90
Nykarleby . . . . .	7	—	7	66	—	66
Total . . . . .	11	4	15	66	90	156
Grand total . . . . .	55	21	76	546	586	1132

The number of graduates from the normal schools in 1908 was 297, which indicates an unusually large attendance in the fourth or upper class.

The expenses of the national system are borne by local resources, of which tuition fees form a small part, and by state appropriations; the latter meet the larger part of the cost of maintenance for rural schools, and about 25 per cent of that for city schools. The total expenditure by the State for primary education amounted in 1908 to 6,761,816 marks (\$1,305,030); the cities contributed also about 4,000,000 marks (\$772,000).

Ample provision for the education of the defective classes is also made in State or State-aided institutions, for which about 690,000 marks (\$133,170) are annually appropriated.

Finland owes to its relation with Sweden two forms of training which have exercised a great influence upon the character and habits of the people, namely manual training or *slöjd*, and gymnastics, based upon the Ling system. Popular education is continued after the brief period of school life by the efforts of associations which maintain peoples' high schools after the model of those of Denmark. In 1908 these schools numbered thirty-eight, with 227 teachers and 1671 students. The State appropriated 266,750 marks toward their maintenance. The associations also foster the national spirit by festivals of music and song, which are held in different parts of the country, and in which trained choirs numbering hundreds of people participate.

**Technical Instruction.** — Special schools of *slöjd* for men and for women are organized throughout the grand duchy, and not only maintain the manual skill for which the people are noted, but supply the simple implements

required for domestic use. The abundance of timber naturally directed the earlier technical training toward wood-work. Gradually the scope of the training has been extended, and there are at present seven well-equipped state technical schools, above 450 schools of arts and trades, and numerous schools of weaving and domestic arts for women, maintained by the communes with aid from the State. The central school of industrial arts at Helsingfors was established in 1875 by the efforts of a private citizen, Mr. Estlander, and placed under the administration of the Finnish Society of Industrial Arts.

Finland has also made comparatively large provision for the training of agriculturists by means of dairy schools, schools of horticulture, schools of agriculture, etc. The crown of the system is the Agricultural Institute at Mustiala, founded in 1840. It comprises at present a section of agriculture with accommodations for forty-two students, and a higher course in dairy work for ten students; to the latter women are admitted. There is also a higher school of forestry at Evois, with accommodations for thirty-five students. According to the latest official report, the number of students preparing in these various classes of schools for industrial careers was as follows: —

SCHOOLS	STUDENTS
Schools of <i>slöjd</i> . . . . .	2300
Industrial schools . . . . .	1060
Schools of arts and trades . . . . .	1477
Schools of agriculture, horticulture, forestry, etc. . . . .	1340

For the above schools the State appropriates annually about one and a quarter million marks (\$241,250). There are also seven schools of navigation, with 175 students, and fifteen schools of commerce, with 1270 students, which receive an annual subvention from the State.

**Secondary and Higher Education.** — The first secondary school (gymnasium) in Finland was founded in 1630 at Abo, and placed under the ecclesiastical authorities. Ten years after a university was established at the same place, to which the gymnasium served as a preparatory school. The course of instruction, which included the studies of the *trivium* and *quadrivium*, was intended to prepare young men for the service of the Church and the State.

The influence of Comenius, who was called to Sweden in 1649 to assist in the reform of the school code, extended to the Finnish province, and as the number of secondary schools increased, there was a noticeable tendency toward freedom and flexibility in their curriculum. An act of 1872 removed secondary schools from ecclesiastic control and placed them under the civil authorities. At that time three classes of secondary schools were recognized, namely, *lyceer* (lyceums), *real-skoler*, and the higher schools for girls; these were classified together as *clementarlaroverken*, implying the stage preliminary to university

studies. The lyceums are divided into the inferior, which have a four years' course, and the higher, an eight years' course; the latter, or full-course lyceum, prepares students for admission to the university; and in like manner the courses of the *realskoler* lead to the technical high school.

According to the latest official statistics (1908), the twenty-six state lyceums for boys had 427 professors and 6426 students, and the seven state *realskoler* for boys 103 professors and 621 students. There were also sixteen state secondary schools for girls, with a force of 244 teachers and 3419 students. This public provision was supplemented by private secondary schools of various types, with an enrollment of 11,722 pupils (4220 boys, 7502 girls). For the current expenditure of secondary schools, the state appropriation in 1908 amounted in round numbers to 5,000,000 marks (\$965,000). Of this amount 53 per cent went to public secondary schools for boys; 16 per cent to the corresponding schools for girls; the remaining 31 per cent was distributed among the private secondary schools.

The Alexander University was removed from Abo to Helsingfors in 1827, the original buildings having been destroyed by fire. The present constitution was adopted in 1852; but the university has had marked increase in scope and resources since that date. A unique feature of the internal life of the institution is the organization in six "nations," based upon the subdivisions of the grand duchy. Every student must enroll himself in one of these "nations," each of which has a constitution and disciplinary powers of its own after the manner of the "nations" in the older universities. The following table shows the distribution of professors and students by faculties in 1909:—

FACULTIES	NUMBER OF PROFESSORS	NUMBER OF STUDENTS
Theology . . . . .	8	96
Law . . . . .	10	415
Medicine . . . . .	38	185
Philosophy		
History and Philology . . . . .	63	635
Physics and Mathematics . . . . .	27	550
Agricultural Economy . . . . .	11	145
Laboratory . . . . .	7	
Total . . . . .	164	2026 <sup>1</sup>

The income of the university in 1908 amounted to 2,500,000 marks (\$482,500), of which 1,730,000 marks, or 69 per cent, was the state appropriation.

The technical high school is the former Polytechnic Institute reorganized in accord-

ance with a law of Apr. 2, 1908. It comprises five sections, as follows: architecture; engineering; mechanical engineering; chemistry; carpentry. The course of study is four years in the first four sections; three years in the last. The total number of students in 1909 was 349. Students who complete either course and pass the final examination receive the diploma of the school, inscribed with the name of the respective section. Candidates for the doctor's degree must have the diploma of the school, must present a thesis embodying the results of original investigation, and pass a special examination. Like the university, this institution is marked by scholastic breadth and freedom. The prosperity and national character of the Finnish system of education are threatened by the recent dissolution of the Diet and the transfer of its prerogatives to the Russian government.

**FIRE PROTECTION.** — For School Buildings. — The problem of fire protection is one of great importance in the building of schools. No attempt is made here to deal with the purely technical side of the question, but for the general reader the following points include the essentials of fire protection:—

1. Wherever possible, all school buildings, especially in cities, should be of fireproof construction. They are not only safer, but are more economical in the long run. It is perfectly possible at this time to build schoolhouses, as well as other buildings, thoroughly proof against fire from within, without entailing a wasteful expenditure of money; but it is much more difficult, and perhaps impossible, to construct a building that will withstand a conflagration. In general, however, there should be no need of building schoolhouses in locations which will demand protection from the danger of fire from without, for they ought to be so far removed

<sup>1</sup> Includes 440 women.

from neighboring structures that they would be safe from such contingencies. In cities where it seems to be impracticable to isolate school buildings sufficiently from other inflammable structures, so as to protect them from danger, it is nevertheless true that thorough protection from within practically eliminates the danger to the lives of the children in all day schools. When school buildings are endangered from fire in neighboring structures, it would rarely, if ever, happen that sufficient time and warning could not be given to the children to escape in safe and orderly fashion. The best advice, then, that can possibly be given to those whose duty it is to plan and construct our public school buildings is to make them thoroughly fireproof from within, and if possible locate them where they will not be endangered from without. Boarding schools and dormitories demand still greater care in this direction, for here the pupils are more seriously exposed day and night.

Theoretically there should no longer be any need to try to impress upon boards of education the wastefulness of time and the insanitary results of locating a school building on a small lot near other buildings or near dusty streets. It has been demonstrated again and again that, if our children are expected to do their work with the least waste of time and nervous energy, they must be furnished a quiet place in which to do their work. Likewise, investigations have shown that school buildings must be removed a safe distance from other buildings in order to get light in sufficient amount and of the proper quality to save the eyes of the children from unnecessary strain due to lack of light and glaring reflections. Adjacent roadways or streets, in addition to the noise of vehicles, make it almost impossible to keep the air in schoolrooms from filling with dust and dirt of a dangerous character. It is plain, then, that not only for the sake of protection from fires originating outside, but for many other reasons, it is a matter of vital moment that school buildings should be constructed on a large lot in a safe location.

2. All schoolhouses of two or more rooms should be heated by some sort of central heating system. When this is placed in a basement in buildings of wooden construction, the floor joists above the furnace or boilers should be adequately protected by asbestos boards and galvanized iron, or some equally effective protection. The basement floors and walls should be of cement. In those parts of our country where steam or hot water systems are to be preferred to the hot air furnace, and where adequate space is at hand, the boiler rooms may be outside the main structure and the heating medium introduced into the building through pipes from the boilers. Such a plan is safer than the one where the boilers are placed in basements, and also make it possible to get rid of heavy chimneys in the main buildings, for such chimneys are dangerous in times of earthquakes or storms. But

with due care in management, and with fireproof construction, it is not a serious menace to house the heating appliances in the basement. When two or more buildings are sufficiently near together to get their heat supply economically from one source, it is generally better, if space can be spared, and if steam or hot water is used as the medium, to locate the boilers in a detached building.

3. The coal bins, or rooms for other fuel, must be at a safe distance from the fire, and yet not so far removed as to be inconvenient. It is generally convenient to build coal bins underground outside of the buildings, with shutes opening at the surface of the ground into which fuel can be dumped easily. There should also be ashpits, carefully built, into which the cinders and ashes could be dumped without in any way endangering the building. Local conditions will always determine the position of these and their mode of construction. For example, when the basement floor is at or near the surface of the ground, other methods than those suggested must be devised. It is always possible, and in fact altogether necessary where oil is used for fuel, to construct a cistern outside of the building and force the oil into the furnace by an electric or steam-driven pump. On the whole, where oil is properly cared for, it seems to introduce fewer dangers as a fuel than coal or wood.

4. In the country, where stoves must be used in the schoolrooms, the floor about the stove should be protected with tiles or glazed bricks. These, with a little planning, and with but little added expense, can be set flush with the floor, and will neither disturb the general appearance of the room nor be in the way. A jacketed stove (see HEATING OF SCHOOLROOMS) can be made far safer than the ordinary box stove, because the former does not get so hot. The cold air rushing in from without keeps it comparatively cool. The chief danger from fires in those buildings where stoves are used arises from poorly constructed flues, or defective pipes. A jacketed stove, set as just described, can be used with comparative safety, provided the inlet for fresh air is carefully protected against fire.

5. All chimneys or flues should be made of selected bricks, set with the best grade of cement mortar, and have within each a complete stem of well-burnt flue tiling, carefully set and jointed. It is very poor economy to neglect such precautions, for, as noted above, most fires originating in buildings where stoves are used arise as the result of defective flues. It is not infrequent to find in the country a flue constructed of one layer of ordinary soft brick, put together with mortar made of a little lime and much sand. It is only a matter of time until cracks open between the bricks, and then such flues become a constant menace. Another danger comes from improper arrangement of the pipe. In the beginning the joints may fit well; but after heating and cooling many times the upper joints slip lower and lower until

danger is imminent. It is essential, therefore, to so construct flues and so carefully set the pipe that all such dangers may be avoided. It is a singularly strange thing how careless the average American builder is in matters pertaining to fire protection.

6. All electric wiring should be done with thoroughly insulated wire encased in safe conduits, and protected with ample fuse connections. This is a necessary and important precaution, especially in wooden buildings, or those not thoroughly fireproof. The advent of electric lighting has brought much relief, but likewise danger; for hidden wires poorly insulated constitute an ever present menace. Most states have laws relating to electric wiring of public buildings, and insurance companies take especial precautions in this regard.

7. Gas pipes for laboratory, heating, cooking, or lighting purposes should be thoroughly tested, and, wherever possible without obstruction, left free, for inspection and repairs. Explosions and fires are not infrequent consequences of badly placed and imperfect gas pipes.

8. All laboratories, cooking rooms, and forge rooms should have fireproof floors, and as far as possible fireproof walls and ceilings. It is far safer and generally more economical for forge rooms to be placed in separate buildings.

9. School buildings should not be more than two stories high, at least for the primary grades. Three stories are allowable for high school grades where ample stairway facilities are afforded. With such a limit school authorities in cities will find fault; but when buildings exceed these heights, they are endangering the children accordingly. Buildings safely removed from other structures and of thorough fireproof construction may be higher as far as the danger of fire is concerned; but on the basis of other considerations ought to be discouraged. The danger of a stampede is greatly increased in those school buildings more than two stories high. Elevators are generally useless in time of fire, and often positively dangerous.

10. All buildings used for school purposes, and especially if they are constructed of inflammable materials, should be protected by a water supply under sufficient pressure and with hose attachments properly located and always ready to check or put out fires during school hours. This is possible now, even where no public water system exists, for by the use of the pressure tank system elsewhere described (see SANITARY WATER SUPPLY FOR SCHOOLS) water can be kept under pressure and ready at all times.

11. Fire extinguishers should be at hand wherever there is any likelihood of danger, and all teachers, as well as the janitor, should be drilled in their use. Fire extinguishers are valuable only in the early stages of a fire, and must be used quickly and intelligently if any satisfactory results are expected.

**Protection of School Children from Fires.**—

1. All exit doors should swing outward. Even those leading from the classrooms into the halls are safer when so hung, if the halls are wide. Otherwise it is better for these to swing in. The outside doors should all be furnished with an emergency fire lock, so that, while they are securely fastened from without, they can never be so fastened from within that the smallest pupil cannot open them by a light pressure. Such locks are now on the market, and should be used on all larger or medium-sized school buildings.

2. All stairways should be of fireproof construction, especially in wooden buildings. They should be wide, of easy tread, with wide landings and solidly built banisters. The number of stairways should amply meet the demands of all the children gathered at any one time on the second floor. The landings should be in width twice the length of the stair tread.

3. Assembly rooms should be built on the first floor, for it is impossible to institute fire drills for those who do not regularly attend school, and no one can handle an undrilled crowd in an emergency. If built on a higher level than the first floor, the number of exits will be materially limited, and the necessary stairways will multiply the danger many-fold.

4. Hallways should be wide, well-lighted, with no projections, lockers, or hat pegs to interfere with rapid moving toward the exits. These are important considerations from many points of view as well as from that of fire protection.

5. Fire drills should be instituted in all school buildings where a common exit hall is used by two or more rooms. The larger the building and the greater the number of children accommodated, the more imperative the need of fire drills. No specific rules can be given to guide in such drills, for these must be ordered and practiced to suit local conditions; but a few general suggestions may prove beneficial. (a) All books and wraps must be neglected. If one child should attempt to gather up books or wraps, others would do the same thing, endangering all. (b) Each child must know precisely where he belongs in line, and must be drilled to keep this place at all hazards. Crippled children ought to be especially looked after. One or two cripples may disarrange the entire line. (c) It is best to march in time, and some musical instrument will help, not only by its assurance, but by distracting thought from danger and also by regulating the rate of the marching lines. A drum is good for such occasions. (d) All pupils delegated as helpers must be trained to do their work carefully and quickly. (e) The lines ought not to crowd the stairways or halls, and naturally no pupil must have a stopping place from the time he starts until he makes his exit safe from danger. (f) The primary grades should leave first, to be marched a good distance from the building before stopping. To this end, and for other reasons, the primary grades should always occupy rooms on the first floor.

6. Fire escapes in school buildings are only for exceptional cases. The ordinary iron stairs or ladders on the outside of the building are of questionable use. They cannot be used safely by small children, and are likely to cause confusion and panic where their use is attempted. The tubular toboggan escape is much better, especially if easy of access from the upper halls is assured. But if due care is taken in the location and construction of school buildings, and watchfulness on the part of principal and janitor is persistently maintained, the use of the stairs and fire drills will avoid all dangers from fires, save in the event of possible explosions. A thousand children can be drilled so as to make their exit from a well-planned two-story schoolhouse in a minute.

In addition to careful fireproof construction of the building as a whole, it is sane and sensible advice to urge those who build schoolhouses to protect the children by wide halls, wide fireproof stairways, roomy landings, and the isolation of all school buildings from any inflammable neighboring structures. F. B. D.

See ARCHITECTURE, SCHOOL.

**FIRMIN, THOMAS** (1632-1697). — A London philanthropist who spent the greater part of his wealth, amassed as a silk mercer, in experiments for the purpose of improving the condition of operatives in factories. In one of these he employed at one time as many as seventeen hundred hands. He was interested in the industrial training of children found in the streets. At his own expense he had printed large editions of a *Scripture Catechism*, for learning which prizes were awarded. He was a member of the Trust, to which his friend, Thomas Gouge (*q.v.*), also belonged, for distributing Bibles and establishing schools in Wales. He was elected a governor of Christ's Hospital, a charitable educational foundation, in 1673, and took a deep personal interest in the welfare of the pupils. He was also a member of the Society for the Reformation of Manners, established in 1691.

**FIRST SCHOOL YEAR.** — The term is usually applied to the first year of work in the elementary school, which is generally begun at about the age of six years. The term thus leaves out of account any previous years of training in the kindergarten. It is conventionally used to describe the first year of formal education commonly given to children in all American communities. Not infrequently the first-year class at school is termed the *receiving* class or grade.

A quarter of a century ago the work of the first year was mainly given over to instruction in the beginnings of reading, arithmetic, spelling, and penmanship. Three conspicuous changes are apparent in present first-year instruction. These differentiate it sharply from the older practice. (1) The beginning of certain of these subjects is postponed. Penmanship and spelling may be delayed from three to six months, and systematic instruction in arithmetic may not be commenced for six months, a year, or even two years. (2) The teaching of children to read therefore holds the central place in the systematic instruction. Whatever other subjects may be taught, and in whatever manner reading itself may be mastered in connection with history and nature stories, plays, and games, manual training, and similar activities, it is the main object of the first year to advance the child's ability to read so that he may gain new experiences through linguistic presentation. (3) The first year of instruction has ceased to deal exclusively with the mere forms and tools of education, and even the mastery of such conventional facts as the forms of words and the arithmetical combinations is based upon many concrete and interesting experiences intrinsically valuable to the children. Contact with real things of every sort, from the gifts and materials of the kindergarten to the living objects of nature study, is guaranteed as never before. The children are much more active in their ways of learning. A more or less passive memorization has given way to an active absorption. Children learn through manual training, through an active and responsible control of window and school gardens (*q.v.*), through playing, singing, dancing, and dramatization. The subjects read are more closely adapted to the child's vital interests. Dull, formal sentences in the reading book have given way to content that expresses situations appealing to children. Objective, active, and interesting methods of teaching thus characterize the first year of school life more completely than any later year of instruction. H. S.

**FISHER, WILLIAM WARE** (1814-1874). — Sixth president of Hamilton College, graduated at Yale College in 1835, and at the Union Theological Seminary four years later. He was president of Union College from 1858 to 1866. W. S. M.

**FISK UNIVERSITY, NASHVILLE, TENN.** — A coeducational institution for colored people, founded in 1865 under the auspices of the American Missionary Association and the Western Freedman's Aid Commission of Cin-

cinnati. The university was incorporated in 1867. Each boarder is required to give a period a day to some form of labor as directed. A grammar school and preparatory college, normal, teachers' training, music, and theological departments are maintained. Candidates for admission to the college must meet requirements equivalent to fourteen units. The requirements for the normal department are grammar school subjects. There is a teaching staff of thirty-seven members.

**FISK, WILBUR** (1792-1839).—First president of Wesleyan University; graduated at Brown University in 1815. He was family tutor for some years in Maryland; principal of Wilbraham (Mass.) Academy from 1825 to 1830; and president of Wesleyan University from 1830 to 1839. He was active in a movement for the introduction of temperance instruction into the schools. Author of *Science of Education* (1832). W. S. M.

PRENTICE, G. *Wilbur Fisk*. (Boston, 1890.)

**FISKE, JOHN** (1842-1901).—An American author, philosopher, and historian; born at Hartford, Conn., Mar. 30, 1842. He graduated from Harvard College in 1863; in 1869 he was appointed lecturer on philosophy at Harvard, and later became assistant librarian, which position he held until 1879. His earliest recognition came to him as a writer and lecturer on evolutionary philosophy. *The Outlines of Cosmic Philosophy* (1874) is his most extensive and systematic contribution in this field. His evolutionary interpretation of religious problems is best expressed in his *Destiny of Man* (1884), *Idea of God* (1885), *Through Nature to God* (1889), and *Life Everlasting* (1901). The energies of the later part of his life were given to the study of history. A forceful lecturer and a brilliant writer, he did as much to popularize history in this later period as he had done to clarify evolutionary philosophy earlier. Among his more important historical works are the *Discovery of America*; *The Beginnings of New England*; *Civil Government in the United States*; *The American Revolution*; *Old Virginia and her Neighbors*; and *The Dutch and Quaker Colonies in America*. Two of his essays are of particular interest to educators, because of the fundamental importance to educational theory of Mr. Fiske's presentation of "The doctrine of the meaning of infancy." The first of these, *The Meaning of Infancy*, is a brief and simplified restatement of the theories of man's origin and destiny, first suggested in his lectures at Harvard University in 1871, and later expanded in Part Two of the *Outlines of Cosmic Philosophy*. The second of these, *The Part Played by Infancy in the Evolution of Man*, was first presented as an address before the Aldine Club, New

York, May 13, 1895. Taken together, these two presentations of the significance of human infancy constitute our most detailed and valuable elucidation of the doctrine. H. S.

See INFANCY.

**FITCH, EBENEZER** (1756-1833).—First president of Williams College; graduated at Yale College in the class of 1777. He taught school several years in New Jersey; was tutor at Yale College; and in 1790 took charge of the Williamstown Academy, which three years later was incorporated into Williams College. He was president of the new institution until 1815. Author of a *Latin Grammar* (1814). W. S. M.

**FITCH, SIR JOSHUA GIRLING** (1824-1903).—Teacher and educational reformer. Born of Essex parents in Southwark, London, where he began active life as an assistant teacher at the Borough Road School (*q.v.*), which was associated with the name of Joseph Lancaster, one of whose pupils, J. T. Crossley, was at that time its headmaster. After serving as headmaster of a school in Kingsland, and taking his degree at the University of London, Fitch was appointed, in 1852, tutor at the Borough Road Training College of the British and Foreign School Society (*q.v.*), and, in 1856, principal of the institution, an office which he held for seven years. As a teacher, he showed brilliant gifts,—sympathy with his pupils, skill in the presentment of facts and ideas, grace, clearness, and aptness of expression, a keen and sustained interest in a wide range of studies, and a deep sense of the social importance and dignity of the teacher's calling. Fitch's work at Borough Road College was highly valued by Matthew Arnold (*q.v.*), who described with praise his methods of teaching in his report on the college for 1858; and drew the attention of Lord Granville to his merits, with the result that in 1863 Fitch was appointed Inspector of Schools under the Education Department, a position which he held with great distinction and usefulness, through a period of rapid educational development, till 1894. He was knighted in 1896. During his official career he served as assistant commissioner to the Schools Inquiry Commission, 1864-1867; as special commissioner in 1869 to report on the condition of elementary education in Birmingham and Leeds (a prelude to the Elementary Education Bill, 1870); and as assistant commissioner under the Endowed Schools Act, 1870-1877 (*q.v.*). He also prepared an official report on American education in 1888, and on the working of the Free School system in America, France, and Belgium in 1891. He was thus qualified by an almost unique experience to advise the Education Department and the public as to the means of securing closer coördination between elementary and secondary education in England.

Conservative by instinct, he had realized the necessity for public supervision of educational endowments, for the extension of educational opportunities to girls and women, for university reform, and for the establishment of University Colleges in the great centers of population. Moderate opinion in England learned to trust him as a cautious and experienced guide. By his writings, official inquiries, and personal influence he smoothed the way for the acceptance of official action and increased public control in secondary and higher education. In the movement for the improvement of girls' schools he took a leading part. By his lectures on the science, art, and history of education in 1877 and (at Cambridge) in 1881, he greatly furthered the scientific study of the art of teaching, not only in training colleges, but among the men and women teachers in secondary schools. He held strongly that religious education should be kept as an integral part of the school training of every child. While he appreciated the services of the good denominational schools, and approved their continuance as part of the national system of elementary education, he based his main hopes for the future of religious instruction in public day schools upon the united Christian teaching given, without denominational bias, in the Board (now Council) Schools, under the Cowper-Temple clause (*q.v.*).

Fitch's interest in the study of American education was always strong, and his admiration of American educational effort profound. He contributed in 1902 to the Board of Education *Special Reports on Educational Subjects*, Vol. 10, Part 1, an introductory essay upon "The Study of American Education; its Interest and Importance to English Readers."

Urbane, discreet, and persevering, Fitch was a tactful intermediary between the Education Department and the public, and greatly helped in bridging the gulf between elementary and secondary education in England. His diligence in public duty, combined with suave fluency of thought and style, enabled him to render, during a time of rapid growth in governmental influence in English education, a service far greater than that accomplished by many men of greater ability, profounder learning, and deeper insight into the trend of English thought and affairs. He was fortunate in his friends and in his freedom from self-consciousness and introspection. His highest gifts were those of a teacher. He was assiduous in self-improvement, punctual in business, lucid in exposition, dignified in bearing, genial in personal intercourse, and singularly fresh in his varied interests and sympathies to the end of his life. No writings record so accurately as his the normal judgment of cultivated educational reformers in England during the years 1865-1895.

**FIVE FORMAL STEPS OF PRESENTATION.**—See METHOD, GENERAL.

**FIVES AND HANDBALL.**—See HANDBALL.

**FIXATION.**—The process or state in which both eyes are so set or adjusted that a given point in outer space is imaged sharply on both foveæ and is therefore seen single. Adequate fixation involves, thus, the accommodation (*q.v.*) of each eye, and the convergence (*q.v.*) of both. The point fixated in this way is called the fixation point. Fixation is doubtless made possible by the existence in the retina of a central spot of clearest vision (the fovea) from which peripherally vision becomes gradually less distinct.

R. P. A.

**FIXED IDEAS.**—False beliefs of a more or less permanent character, sometimes limited to the beliefs called obsessions (*q.v.*), but often used to include all delusions (*q.v.*). The distinction has been drawn that fixed ideas are concordant, so far as the individual knows, with the environment, while obsessions are usually recognized as foolish. This distinction does not always hold, for certain fear obsessions are thoroughly believed in and are considered to be reasonable by those who have them. The classification of fixed ideas follows that of delusions, although most of them have reference to the autopsychic sphere. Examples of fixed ideas are as follows: (*a*) the idea that an individual has a cancer of the stomach, because he has felt what he thinks is an unusual mass on the right side of the body below the ribs; this idea originated in a fear that he would have cancer because on both the paternal and maternal sides of the family cancer had existed; the idea was dissipated after a careful examination and instruction in the proper location of the stomach; (*b*) the idea that a fatal kind of heart disease existed, the origin of which idea was precordial distress following indiscretions in diet, cured also by careful examination and the administration of a placebo.

These ideas occupy consciousness to such an extent that they often preclude the pursuit of one's usual occupation and bring about disturbances in digestion and losses of weight. They are often found in children at or about the age of puberty. They are primarily produced by what the individual feels is an abnormal

sensation, and they are elaborated by the reading of medical advertisements in newspapers and by the indiscriminate distribution of circulars of patent medicines.

**FLAT.** — See MUSICAL TERMS.

**FLEXIBLE GRADING.** — See GRADING AND PROMOTION.

**Flicker.** — When a series of visual stimulation acts upon the retina at a rate which is too rapid for each stimulation to become fully established in its own character, and yet too slow to produce a fused effect, there is a rapid fluctuation in the quality of sensory experience which is designated as flicker. This flicker is used as the measure of sensitivity, and has significance for the student of sensory processes.

**FLOGGING.** — See PUNISHMENT, CORPORAL.

**FLOOR SPACE PER PUPIL.** — A schoolroom thirty-two feet long, twenty-four feet wide, and twelve and one half feet in the clear between the floor and the ceiling will accommodate forty-five pupils of the lower grammar grades, and forty pupils of the upper grades. This will allow approximately 200 cubic feet of air space per pupil after deducting the amount occupied by furniture, and will permit the desks to be safely arranged with reference to properly placed windows, and at the same time allow ample room for aisles between desks, plenty of room for blackboard workers, and the necessary furniture at the teacher's end of the room. No teacher can do good work in a crowded room; and, what is more important, the pupils themselves need this amount of space for that sense of freedom necessary for undisturbed and unhindered work. In most European countries no uniform norm is accepted. In the primary grades they prescribe much less cubic air space than for the older pupils. This seems to be a mistake, for the following reasons: (1) More unobstructed room is needed for sand tables, and various kinds of manual work in rooms for primary classes than in the higher classes, for such work in the advanced grades is better done in special rooms. (2) More free space is needed in the primary

grades for marching, calisthenic exercises, and all other active games and class work than is needed in the upper grades. (3) Little people are more sensitive to bad air, more easily distracted by close neighbors, and need more individual attention from the teacher. Hence the aisles should be correspondingly wider. (4) The children of the primary classes vitiate more air in proportion to size than larger pupils, and hence need comparatively more space. (5) It is false economy to overburden a teacher of the primary grades with too many pupils, and it likewise limits her work too exclusively to book learning.

It is important, then, to hold approximately to this standard, especially by reason of the fact that forty-five pupils are enough for any teacher to manage successfully. A few years ago much more was made of the amount of space per pupil from the point of view of ventilation. But with any satisfactory mechanical system of ventilation, sufficient fresh air can be furnished, even for a room much more crowded than the plan suggested above would permit. But when there is a dependence merely on gravity for changing the air in schoolrooms, overcrowding becomes a serious matter.

In warm climates, or during those seasons when the outside air registers but a few degrees lower than that needed in the schoolroom, it will be practically impossible to ventilate a schoolroom in any acceptable way with less than 200 cubic feet of air space available per pupil; and even with windows all favorably placed, it will require the utmost care on the part of the teacher to keep the air passably pure with this allowance of space. Only on the basis, then, of a satisfactory system of ventilation can one with any degree of certainty safely prescribe 200 cubic feet of air space per pupil. Anything appreciably less than this will, for the reasons mentioned, prove unsatisfactory. In insisting on an air space of at least 200 cubic feet per pupil, it is known, as suggested above, that this amount is in excess of that often found in practice, and that prescribed as allowable by many European authorities. But it should be insisted that with the growth of a more active personal participation of the child in his school work, and under our form of government, where the children must be trained in cooperative work, this amount of space is not only a conservative estimate, but one which all teachers and school authorities should demand as a minimum.

**FLORENCE, ROYAL INSTITUTION OF HIGHER STUDIES, ITALY.** — In spite of the general progress and wealth of Florence, it was not until 1349 that a papal bull sanctioning the establishment of a *Studium Generale* was obtained. Attempts had been made in

1321 to secure the professors of the University of Bologna, but without success. The university, however, never really attained to much importance. While much money was devoted to salaries, the teachers could not be induced to stay, nor could the students be attracted to a town which did not offer the same facilities for cheap living as other university towns. The faculties of law and theology flourished intermittently. During several periods the university was entirely suspended, as in 1354-1357, 1378, and about 1412. In 1360 Leontius Pilatus lectured on Homer; in 1373-1375 Boccaccio (*q.v.*) held the chair in poetry and lectured on Dante; and in 1396 the first chair in Greek in any university was held by Chrysoloras (*q.v.*). In 1388 new statutes were drawn up for a reorganized institution. The university continued until 1473, when it was decided to transfer it to Pisa.

The present institution was established in 1859. It has faculties of philosophy, natural and physical sciences, medicine, and pharmacy. The number of students in 1910-11 was 482, a little more than half being in the faculty of medicine.

**FLORIDA STATE COLLEGE FOR WOMEN, TALLAHASSEE, FLA.** — Established in 1905 by the state of Florida. A graduate school, college of arts and sciences, normal school, and schools of art, music, and expression are maintained. Admission to the college is granted upon certificate or examination, amounting (after 1913-14) to 14 units. The requirements for entrance to the normal school are the work of the eight grades. The college offers six groups of studies, leading up to the A. B. and B. S. degrees. There is a faculty of twenty-five members.

**FLORIDA, STATE OF.** — Ceded to the United States by Spain in 1819; organized as a territory by Congress in 1822; and admitted as the twenty-seventh state in 1845. It is located in the South Central division, and has a land area of 54,240 square miles, being about the size of New York and New Jersey combined. For administrative purposes it is divided into forty-six counties. In 1910 Florida had a population of 751,139, and a density of population of 13.8 per square mile.

**Educational History.** — Excepting possibly some Spanish mission schools, nothing was done toward the establishment of schools in Florida until 1831. In that year the Florida Educational Society was formed, the object of which was to diffuse information on the subject of education and to secure the establishment of a school system for the territory. In the same year the Governor was authorized by law to appoint three commissioners to examine into the need of education and to report upon a system of schools suited to the needs of the territory. A ladies' educational society

was also formed to further the movement for schools, and much interest in education was awakened. In 1832 a Fellenberg Manual Labor School was provided for at Tallahassee, and a common school at St. Augustine. The latter reported 137 pupils in attendance in 1832, but the school soon closed and the movement for schools died out. In 1835 the Registrar of the land office was instructed to select and secure "the various lands granted by Congress for schools, seminaries, and other purposes." In 1839 the first school law was enacted. This directed that three trustees should be elected in each township to care for and lease the sixteenth section lands, and to apply the income to the support of schools. Many townships at this time did not have a single inhabitant. In case schools did not exist, the trustees were to organize and support them. In 1843 the sheriffs of the counties were given the duties previously given to the trustees, and with special instructions to look after the education of the children of the poor. In 1845 these trustees were directed to report annually to the probate judges of the counties, who were to act *ex officio* as superintendents of schools. The judges were to consolidate the returns and forward them to the Secretary of State who was to lay the results before the General Assembly. No taxes were levied, nor were the schools free, except to the poor.

The first constitution of the state made no provision for education other than to direct that the lands given by Congress for the benefit of schools and institutions of learning should forever be devoted to that purpose alone. In 1849 the first school law after the admission of the state was enacted. This provided for the establishment of common schools for white children, and directed that the five per cent received from the United States for the sale of lands within the state, all escheated estates, and all property "found on the coast or shores of the state" should be added to the school fund. In 1850 the Registrar of Public Lands was made *ex officio* State Superintendent of Common Schools, and the counties were authorized to levy a county tax of a maximum of \$4 for each child of school age. Only two counties ever availed themselves of this law. In 1852 the city of Tallahassee was allowed to levy a city school tax to help support its own schools; and about this time the sixteenth section funds, heretofore belonging to the townships, were consolidated by permission of Congress into one state fund for the benefit of the children of the state as a whole. In 1852 the East Florida Seminary was established at Ocala. It was opened in 1853, and in 1866 was removed to Gainesville. In 1856 the Florida Institute at Tallahassee was accepted by the state as the West Florida Seminary. Both of these institutions were established from the seminary lands granted by Congress at the time of the admission of the state. By the school law of

1853 the apportionment of the school fund within the counties, then amounting to thirty cents per school child, was given to the County Commissioners, who were made *ex officio* a County School Board and were authorized to add to the sum received from the state "any sum which they may deem proper to be paid out of the county treasury." Only two counties ever made any appropriation, and the state money was commonly used to subsidize private schools and private teachers. After this law nothing further was done toward the establishment of a system of free public schools until 1869. The census of 1840 showed that there were eighteen academies and grammar schools, and fifty-one primary schools in the state; in 1850 there were ten academies and sixty-nine common schools; and in 1860 there were ninety-seven common and public schools, 138 academies and private schools, and the total state income for educational purposes was \$75,412. Of this amount \$22,386 was derived from the school fund income. The Civil War put an end to all of these efforts, and the permanent school fund and the seminary fund were both spent for "arms, ammunition, and other purposes" connected with the Confederacy.

The constitution of 1865 merely repeated the provision of the constitution of 1838 regarding the preservation and use of the school lands, but the constitution of 1868 made full and definite provision for a free state school system for the benefit of all. An *ex officio* State Board of Education was created; the Governor was required to appoint a State Superintendent of Public Instruction for the state and a county superintendent of common schools for each county; the legislature was instructed to provide a uniform system of common schools and a university, and to liberally maintain them, and in these tuition was to be free and the schools equally open to all; the sources of the school fund were enumerated and increased; a state tax of not less than one mill, a poll tax, and a county tax equal to at least one half the amount received from the state were to be levied for the maintenance of schools; and a three months' school was to be maintained in each school district of the state. The school law of 1869 carried these constitutional provisions into effect, and not only marks the beginning of free public schools in Florida, but also laid the foundations of the present school system. Progress under the new law was discouragingly slow for some years. There was an apathy engendered by long years of neglect, and there were few teachers and fewer schoolhouses. The best schools during the first decade under the new system were those aided by the Peabody Fund. About 600 schools had been organized by 1874, and by 1880 there were 1504 public schools, and an expenditure for public education of \$172,178, or about \$3 for each child

enrolled. The first teachers' institutes were held in 1879, and in 1886 a State Teachers' Association was organized. In 1880 the East Florida Seminary organized a normal department for the training of teachers; in 1883 the Florida State Agricultural College was opened at Lake City, and the State Blind and Deaf Institute at St. Augustine. In 1885 a new constitution was adopted, which made certain changes in the school system. The State Superintendent of Public Instruction and county superintendents of public instruction were now to be elected instead of appointed by the Governor, and the salary of the State Superintendent was cut in half; the Governor and the State Treasurer were added to the State Board of Education, and the board was given power to remove school officials for cause, to manage the school funds, and to supervise the "schools of higher grades" in the state; the State School Fund was still further enlarged; a county school tax of not less than three nor more than five mills was required; a county school fund was created; school districts, city and town districts separate from the county, and district taxation up to three mills were authorized; the instruction of white and colored children in the same school was forbidden; and the legislature was directed to establish one or two normal schools at its first session. This new constitution, with the subsequent legislation, founded the present school system. In 1887 a normal school for colored teachers was established at Tallahassee, which in 1891 became the Florida State Normal and Industrial College for colored students. A normal school for white teachers was established at De Funiak in 1887. In 1889 the legislature abolished the trustee and district system; reduced the county boards from five to three members each; and gave to the county board of public instruction the employment of teachers and the control of the schools of the county. In 1893 county boards were made elective, the uniform examination law for teachers' certificates was passed, and a bill providing for state aid (\$50,000 per year) for high schools and a standard state course of study for high schools and for common schools was enacted. In 1894 the state constitution was amended so as to provide for the distribution of the state school fund to the counties on the basis of average daily attendance instead of school census, and in 1904 the constitution was still further amended so as to raise the maximum limit of county taxation from five to seven mills. In 1907 county superintendents were given a definite salary by law, varying from \$600 to \$2400 a year; the state aid to high schools was increased to \$65,000 per year; \$60,000 per year was appropriated to extend the term two months in those schools having an average daily attendance of 80 per cent of the average monthly enrollment; and \$40,000

to extend the term one month in all schools not receiving aid under any other provisions.

**Present School System.**—As at present organized, the school system of Florida is as follows. At the head of the system is a Superintendent of Public Instruction, elected by the people for four-year terms, and an *ex officio* State Board of Education. The Superintendent has "general oversight, charge, and management of all matters pertaining to public schools, school buildings, and grounds" in the state. He calls the county superintendents together in conventions; holds teachers' institutes and engages instructors for the same; apportions the state school money to the counties; prepares the questions for county examinations, and holds examinations for state certificates; nominates persons to fill vacancies in county boards of education; prepares forms and blanks, and makes an annual report to the Governor. The State Board of Education has the management of all school lands and the investment of all school funds; acts as a court of appeal on disputed school questions; may remove any subordinate officer in the schools for incompetency, neglect of duty, or other sufficient cause; and fills all vacancies in county boards of education until the next election.

For each county there is a county superintendent of public instruction, elected by the people of the county for four-year terms, and a county board of public instruction consisting of three members elected for two-year terms, one from each of the three school board districts into which each county is divided. The county superintendent is required to inspect the schools and to advise with parents and school officers; to keep records of each school; to decide disputed school questions; to look after school buildings and funds; to conduct teachers' examinations and issue county certificates; to report the collection of poll taxes and to take the school census; to act as secretary and executive officer of the county board of public instruction. These boards in each county hold the title of all school property, except in special-tax districts; select school sites and locate schools as needed; employ teachers, and pay them for their services; appoint one supervisor for each school, on the recommendation of the patrons and the nomination of the county superintendent; do whatever is necessary in their judgment to advance the interests of the schools in their charge, possessing large discretionary powers in this matter; may establish high schools; must make a monthly and an annual financial report to the county clerks, and an annual report to the State Superintendent; select and adopt a uniform series of textbooks, and prescribe a uniform course of study for the schools of their respective counties; estimate and levy the amount of county school tax needed to conduct the schools for the ensuing year; ap-

point a county grading committee of three teachers to assist the county superintendent in conducting teachers' examinations; fix the time for the opening of the schools of the county; order elections for the creation of special-tax districts; and subdivide each county into three approximately equal school board districts for the election of members of the county board of public instruction, and alter the boundaries of the same. The patrons of each school recommend, the county superintendent nominates, and the county board of public instruction appoints one supervisor for each school in the county, special-tax districts excepted, whose duties are to supervise the work of the school and to report monthly to the county superintendent. This is all that is left of the district system of school administration in the state, except in special-tax districts.

By a petition of one fourth of the taxpayers and an affirmative vote of a majority of the votes cast at a special election called for the purpose, any city, town, community, or subdivision of the county may organize itself as a special-tax district to be governed by three trustees, elected for two-year periods. The board of trustees, so elected, supersedes the supervisor, but the schools still remain under the control of the county board of public instruction. The trustees in special-tax districts are given power only to nominate teachers to the county board for appointment; to expend all special tax raised by them in any equitable manner they may deem best; to estimate the rate of special tax to be voted for the ensuing two years; to admit outside children to the schools; and to supervise the schools and report to the county superintendent and county board.

**School Support.**—The state originally received 908,503 acres of land from the 16th section grants made by Congress to the states for common schools, and four townships of land (92,160 acres) for two seminaries of learning. A portion of this was sold before the war, but the proceeds of such sales were lost in the struggle. About one third of the 16th section land is still on hand, and is classed as unproductive land, not under lease, without any value attached to it. The total permanent school fund of the state, at last report, was \$1,129,667. The interest on this, together with a state one mill property tax, is apportioned to the counties on the average daily attendance of the preceding year. Each county is required to levy a county tax of not less than 5 mills, and a poll tax of \$1, to be added to the fund received from the state. The average county tax levied in 1909-10 was 6.84 mills, thirty-two of the forty-six counties levying 7 mills, the lowest tax levied being 5 mills. Special-tax districts, of which there were 466 in 1908, may also levy additional taxation up to 3 mills. The state also makes additional

appropriations of \$65,000 annually in aid of high schools; \$60,000 annually in aid of all common schools, attaining an average attendance of 80 per cent on the total term enrollment; and \$40,000 annually to be apportioned to the counties in proportion to their property valuation, to extend for one month the schools not receiving aid under either of the two plans just mentioned. The total state contribution in 1906-1907 was equal to 13.65 per cent of the total sum raised.

**Educational Conditions.** — Of the population of 1900, 43.6 per cent were negroes, and 95.5 per cent were native born. In twelve counties the blacks outnumber the whites, and in two counties they outnumber the whites four to one. The percentage of illiteracy in Florida (21.9 per cent), according to the Federal census of 1900, was somewhat lower than that for the other Southern states. For the two races the figures were 8.9 per cent for the white and 38.4 per cent for the black. The average value of land, furniture, equipment, and schoolhouses of the state is about \$1000 each, which is also higher than is the case in neighboring states. For buildings alone the average value is approximately \$800 for white and \$300 for black schools.

The rural schools are but partially graded. Manual training is not listed as taught in any city or town in the state. Rural graded schools, which prepare pupils for the high school grades, are now being developed in many places.

**Teachers and Training.** — According to the statistics furnished, the negro teachers are a more permanent class than the white teachers, the average teaching experience of negro males being seventy-nine months as against fifty-two months for white males, and forty months for negro females as against thirty-six months for white females. Seventeen per cent of the white teachers and 19 per cent of the colored are graduates of normal schools. For the training of new teachers the state maintains the State Normal and Industrial School at Tallahassee for negro teachers, while the educational department of the University of the State of Florida and the normal department of the Florida Female College serve as normal schools for the white race. In addition, the state maintains two summer schools of two months each for the instruction of white teachers, and one summer school of six weeks for the instruction of colored teachers. For the maintenance of these summer schools the state makes an annual appropriation of \$4000, and \$2500 additional to pay the traveling expenses one way of all teachers or prospective teachers attending these schools. The teachers' institute, with required attendance of all teachers, as known elsewhere, has not as yet been made a part of the state school system. Voluntary teachers' associations are held, and these enrolled one sixth of the white and one seventh of the colored teachers.

**Secondary Education.** — Since 1903 the state has offered aid, as noted above, to rural graded schools, and to junior (two-year) and senior (four-year) high schools. Rural graded schools, as defined, must be located in towns of less than 500 inhabitants, or three or more miles from any town or city of over 500 inhabitants. Two public high schools and three denominational institutions offer secondary instruction for the colored race. Many of the high schools are combined grammar and high schools.

**Higher and Technical Education.** — The University of the State of Florida, at Gainesville, for men, and the Florida Female College, at Tallahassee, for women, stand as the culmination of the public school system of the state. The former now embraces the Agricultural and Mechanical College, formerly located at Tallahassee. The Florida State Normal and Industrial School, at Tallahassee, offers mechanical and agricultural instruction for the colored race. The state also maintains the Florida Institute for the Blind, Deaf, and Dumb at St. Augustine. In addition to the state institutions, two private and denominational institutions offer work of collegiate grade. E. P. C.

**FLORIDA, UNIVERSITY OF, GAINESVILLE, FLA.** — An institution established by act of legislature in 1905, which established at the same time the Florida State College for women and abolished the Agricultural College at Lake City (founded in 1884, and from 1903 to 1905 known as the University of Florida), the Florida State College at Tallahassee (*f.* 1856), the Normal School at De Funiak Springs, the East Florida Seminary at Gainesville (*f.* 1852), the South Florida College at Bartow, and the Agricultural Institute in Osceola County. A sub-freshman class is also maintained. The entrance requirements to the full courses are equivalent to twelve points of high school work, and admission is by examination or certificate from an accredited high school. Six courses are offered, leading to the degrees of A.B. in arts and pedagogy, B.Sc. in general science, engineering, and agriculture. Short two-year courses are provided on a basis of the common school branches. The university is under the supervision of a Board of Control, and is maintained out of state appropriations, and the income of the Agricultural College Fund, the Morrill and similar funds, and the East Florida Seminary Fund. The student enrollment in 1909-10 was 186. There is a teaching staff of forty-six.

**FLORIO, JOHN.** — Writer of Italian textbooks in England; born about 1533, was the son of Michael Angelo Florio, preacher to the Italian Protestant refugees in London, 1550. It was of this church that Roger Ascham spoke in the *Scholmaster*, when he condemned courtiers for attending the service only to hear the language and not for devotional purposes. John Florio's father taught Italian in London. He translated a Latin Catechism into Italian, 1553 (?) and wrote in Italian a life of Lady Jane Gray. But it was his son John who is especially to be connected with systematic teaching of Italian in London. John Florio was probably educated first on the Continent, and then entered Magdalen College, Oxford, in 1581. He was connected with the household of the Earl of Southampton, and had been tutor in foreign languages to Robert Barnes, son of the Bishop of Durham (Einstein, *Italian Renaissance in England*, p. 102). Florio was teacher of languages to the young Prince Henry, son of James I. He became reader in Italian to Queen Anne (wife of King James I) in 1603. Florio was married to the daughter of Samuel Daniel, the poet. Florio is best known by his translation from the French of Montaigne's *Essays* in 1603. But he especially aspired, as he says himself, to do for Italian in England what Sir Thomas Elyot and Bishop Cooper had done for Latin, and what the Estiennes had done for Greek, and with this end before him compiled *A Worlde of Words: a most copious and exact Dictionarie in Italian and English*, Lond. 1598. The second edition was entitled *Queen Anna's New Worlde of Words*, and was published in 1611. The third edition was revised by Giovanni Torriano and published in 1659 — with an English-Italian part added by Torriano. Florio's other Italian textbooks were *First Fruits, which yielde familiar speech, merie proverbes, wittie sentences and golden sayings, also a perfect Introduction to the Italian and English Tongues*, Lond. 1578. *Secound fruites to be gathered, of twelve Trees (q.v.) but delightosome tastes to the tongues of Italian and Englishmen. To which is annexed his Garden of Recreation, yielding six thousand Italian Proverbes.* Italian and English, Lond. 1591. The latter part was also published separately in Italian as *Giardino di Recreazione*, Londra, 1591. The method of teaching by proverbes is paralleled by John Clarke (*q.v.*) and Erasmus' *Adages*, and was thus a recognized teaching method of the times. F. W.

**FLUCTUATION OF ATTENTION.** —

Whenever one attempts to hold an experience, either sensory or ideational, steadily in consciousness, he experiences a succession of wavering intensities. At one moment the experience is vivid and intense; a moment later it is less intense, frequently disappearing entirely from consciousness. For example, if an observer looks steadily at a faint light, it will be seen to come and go. This fluctuation is due to a series of retinal conditions which arise during the progress of the stimulation. Pillsbury distinguishes between fluctuations in organs of sense, illustrated in the last example, and fluctuations of attention. The latter are, according to his experiments, somewhat slower than the fluctuations in sensory processes. For the most part sensory fluctuations and fluctuations in attention have been regarded as identical in type. Both have been traced to the inability of nervous tissue to continue indefinitely its activities. When the retina stimulated by constant light reports to the central nervous system varying intensities of sensory excitation, this is held to be due to the intermittent activities of nervous tissue. In the same way when one attempts to hold an idea vividly before his consciousness, but fails to do so with complete success, it may be assumed that his central nervous tissue, like the sensory tissue, is incapable of indefinite activity at the same level of intensity. PILLSBURY, W. B. *Attention.* (London, 1908.)

**FOLKLORE.** — The science of folklore, if science it is, has the unusual distinction of bearing an English name. The general custom of the English language from the beginning has been to give names of Latin and Greek origin to scientific studies, such as the older names astrology, mathematics, etc., and the names of the newer sciences, biology, sociology, anthropology, etc. The native name of the science of folklore is suggestive both of the origins of the science and of the reasons why its standing as a science has been frequently called in question. The science owes its origin to the world-old interest which the more inquiring among men have always felt with respect to the habits and customs of the society of which they were members. The study gives expression to a general popular interest, and therefore appropriately has taken a generally intelligible English name. This popular interest in social custom and tradition has seldom been developed, however, with any approach to rigid scientific method. Every one observes social custom with a certain degree of intelligence, but few take the trouble to test their own observations in a critical spirit or to weigh the evidence upon which the reported observations of others are supposed to be based. It results consequently that much of

the material in folklore research is gathered with an easy credulity that makes it altogether unreliable as ground for scientific generalization. That this weakness of much so-called research in folklore is not inherent in the subject, but is due to the untrained character of the popular observer is sufficiently proved by much work that bears the test of the most rigid standards of scientific method.

As a branch of scientific research, folklore may be regarded as one division of the general science of anthropology. Its specific definition has been given as "the science of tradition," and tradition, in the sense in which the term is here used, means "the whole body of the lore of the uneducated. It thus includes customs and institutions, superstitions and medical practice, and many other things besides stories." (E. S. Hartland, *Folk-lore, What is it and what is the good of it?* pp. 6-7.) The material of folklore is thus seen to be made up of popular narrative, such as expresses itself in myths, epic, romance, and legend, of customary practices, such as the observance of funeral or marriage rites, of baptism and the thousand other traditional customs of society, of superstitions, reasonable and apparently unreasonable, like the superstition of the evil character of the number thirteen or the power, benevolent or malevolent, of supernatural beings, etc. It is limited to the lore of the "uneducated," because it is mainly in the life of this class that traditions arise and are developed in a natural and untrammelled way. The tendency of higher and more artificial forms of society is to cast discredit upon popular tradition and to introduce an element of consciousness which is destructive of the naïve self-revealing character of genuine primitive traditions.

Such being the materials of the science of folklore, the purpose of it is to determine by means of extended and comparative study the general mental characteristics which are the common possession of the human race. "The human mind, alike in Europe and in America, in Africa and in the South Seas, works in the same way, according to the same laws. And the aim of the science of tradition is to discover those laws, by the examination of their products, the customs and beliefs, the stories and superstitions handed down from generation to generation, to ascertain how these products arose and what was the order of their development, and so to coöperate with physical anthropology and archæology in writing, as it has never yet been written, the history of civilization." (Hartland, *ibid.*, pp. 7-8.) The sources of the material for the science of folklore are found first of all in the traditions of "uncivilized" peoples, for here primitive traditions are most likely to persist with the least artificial and extraneous addition; secondly, in the traditions of the "uneducated" portion of civilized societies, where popular

customs are least subject to critical examination or to corruption by contact with literary and learned practices; and finally, in the survivals of genuine primitive traditions which linger in the social customs even of highly civilized peoples, for example, many of the rites of baptism, marriage, and burial current in conventional societies.

As a separate subject, apart from the general sciences of anthropology (*q.v.*) and ethnology, folklore has as yet found no place in the academic curriculum of colleges and universities. Much of the attention which is given to the origin and growth of early traditional literature, the myth, the epic, etc., and to the explanation of early ritualistic and gnostic literature, properly comes under the head of folklore, but is not so designated in the classification and organization of academic courses in these subjects. As a field of research in itself, folklore has been most zealously cultivated by the non-academic public, especially through the organization of folklore societies. The Folk-Lore Society of London has issued numerous publications since the year 1878, and is still active. The American Folk-Lore Society, with headquarters in Boston and with many branch societies, since the year 1888 has issued many interesting and important numbers of its *Journal of American Folk-Lore*. Owing to the facts that the materials for observation are accessible on all hands and that no technical methods are necessary for the gathering of these materials, the study of folklore has been prosecuted with zeal and intelligence by a large body of popular investigators.

Apart from its scientific interest as a branch of the science of anthropology, the study of folklore is of educational significance mainly in connection with the elementary school. The subject is obviously not one to be taken up in any formal manner in the elementary school; but a knowledge of some of its methods and purposes is implied in the use of much of the narrative material now employed in elementary instruction. Popular traditional narrative is peculiarly suited to the mental needs and capabilities of children before they are prepared to appreciate the more subtle and refined works of conscious literary art. The child, repeating in some degree the history of the race, understands and enjoys what the race has produced in its own primitive childhood. Beginning, therefore, with the earliest anthropomorphic fables and animal stories, and passing down through the myths and fairy tales of the race, the hero tales, which form the material of early epic and legendary narrative, and the more idealistic romances of the tales of adventure and chivalry, the child reviews in succession the great motive forces, in their simplest and broadest expression, which gave life and energy to man's earliest literary impulses, and which, to a large extent, still continue to give life to all the products of the

literary imagination. (See CULTURE EPOCH.) In general it will be found that the more popular and unliterary the form of a traditional narrative, the more picturesque and interesting, both in phrasing and in content, it will be. It has very rarely happened that a literary revision of a genuine popular narrative has improved it, so far, at least, as its presentation to children is concerned. The best the literary reviser can do is to transcribe, as Grimm did in his *Märchen*, the form of the story which has been worked out in the practical school of popular experience. In this connection attention may also be drawn to the fact that the popular origin and evolution of traditional narrative does not necessarily imply a low degree of art in such narrative. The methods of popular narrative are as exacting as those of written literary art, and a story, formed and elaborated by many successive generations of traditional telling, may have reached a final and perfect form, which, if it can be caught in its genuine popular form, is not to be improved by conscious artistry. The mere writing down, as in the case of Homer and the other great epics, is an accident of circumstance, and has little to do with the creation of the narrative itself.

The forms of folk tales most frequently used for purposes of instruction in the teaching of elementary students are myths, fairy tales, and fables. Stories of the first kind, in which there is usually a narrative of human events involving supernatural persons and expressing a traditional, popular conception of natural phenomena (such as the Apollo myths), or of historical or supposedly historical events (such as the Trojan wars of Homer), are widely distributed among all peoples. They are obviously related in their origins and development to the growth in religious thought and in national self-consciousness of the peoples whose life they respectively express. Most of the great epics of the world have a mythical foundation, a strong mythical element.

The fairy tale, on the other hand, differs from the myth mainly in that its interest is not so comprehensive, so epic. Supernatural characters also appear in the fairy tale, but here these characters are the minor deities, the *genii loci*, of more distinctively popular tradition. The fairy tale, moreover, has frequently bound up with it many of the characteristics of the popular folk tale, such as moral teaching, animal transformations, ingenious plot, and droll situation. If the myth be characterized as the product of primitive imagination, the fairy tale may be described as the product of primitive fancy.

The third type of folk tale, the fable, as the term "fable" is now used, comprises short stories containing moral lessons in which the actors are either altogether or partly animals or inanimate objects of nature. The ultimate origin of stories of this kind as survivals of

primitive animism seems probable. Historically, however, the great body of fable literature can be traced back to two sources, Greek and Indian, from which it has been diffused throughout the nations of modern Europe. Among the early Romans of the south of Europe and among the Teutonic peoples of the north there was no traditional fable material of native origin. The two sources from which the great body of European fable literature has been derived are, first, the Greek fable, which was developed as early as the sixth century B.C., at which time Æsop (*q.v.*), according to the testimony of Herodotus, lived. It is not to be supposed that Æsop invented the Greek fable, which bears all the marks of a traditional folk tale, but it has been plausibly surmised that Æsop became the name to which the floating literature of popular fable attached itself because Æsop applied this popular fable literature to a new purpose, namely, to the discussion of political matters when free speech was dangerous under the Greek tyrants. That the Æsopic fable was an independent development in Greece seems to be adequately established, though later the original stock of Greek fables was largely increased by borrowing from the Indian fable.

The main applications of the Indian fable were religious. Originating, like the Greek fable, in folk tales of animistic coloring, the development of which was greatly encouraged by the Oriental belief in metempsychosis, the Indian fable was utilized in the popular religious instruction of the Buddhists very much as the lives of the Saints were used by the medieval Christian preachers. These stories were gradually collected under the name of *Jataka*, or stories of the Buddha's former births; and each tale consists of a story of the past, *i.e.* of the former birth, and a story of the present, from which the story of the past arises by suggestion, and the whole concludes with one or several moral statements summing up the teaching of the story. Collections of this nature assumed various forms in the East, the most important, after the *Jataka*, being the *Panchatantra*, the *Hitopadesa*, and the *Kalilah and Dimnah*. The history of these collections, of their combination with the body of Greek fable, and of the diffusion of this general collection of Indian and Greek fable would be the history of by far the greater part of the fable literature of medieval and modern European literature.

**FOLK PSYCHOLOGY.** — This term refers, when used in a strict sense, to the body of scientific knowledge which has been accumulated with regard to the special mental traits of definite communities or tribes. In a somewhat more general sense it is used as a synonym for social psychology (*q.v.*). C. H. J.

**FOLK TALES AND FOLK LITERATURE.** — See FOLKLORE.

**FOLLEN, CHARLES** (1796-1840). — Author of the earliest texts prepared in America for the study of German in schools; was educated in Germany, and was eleven years an instructor and professor in Harvard College. His German readers and grammars were published from 1826 to 1835. W. S. M.

**FOOD AND FEEDING OF SCHOOL CHILDREN.** — **Nutrition.** — In the feeding of school children there should be intelligent coöperation between parents and teachers, between the home and the school. Proper nourishment is an essential condition of efficient school work. The primary responsibility rests upon the home, but under modern conditions the school has a duty in this matter,

also. Even where the school has no share in the actual feeding of children, it can nevertheless often have an influence by advice and suggestion. Parents should have an elementary knowledge of common foods and their composition in order to regulate their children's diet intelligently and provide wholesome school lunches. They should know that there are three main classes of food: first, those rich in proteins — lean meat, eggs, fish, milk, and the like; second, the so-called fuel foods, the various carbohydrates — cereals, bread, potatoes, cake, sugar, preserves, etc., together with the fats; and third, those foods which consist chiefly of water — green vegetables, oranges, tomatoes, and the like.

The question of just how much food is needed by children at different ages and what proportion of protein, fat, and carbohydrates should be provided is not settled. Many estimates have been made. An American standard by Atwater is as follows for an adult engaged in moderate muscular work: 125 grams of protein and 125 grams of fat, and 450 grams of carbohydrates, with a fuel value of 3520 calories.<sup>1</sup> Children of six to nine are supposed to need about half as much! Cameron approves the estimate of Sommerfeld, according to which children between five and eleven require on an average per day the following amount of food: —

AGE	PROTEIN GRAMS	FAT GRAMS	CARBOHYDRATE GRAMS
5-7 . . .	50-58	30-43	145-197
8-10 . . .	60-88	30-70	220-250
10-11 . . .	68-86	44-85	211-270

Dr. C. F. Langworthy has estimated the amount that children and adults in this country actually do eat as follows: "The average adult in the United States is daily supplied with 100 grams of proteins, 150 grams of fats, and 350 grams of carbohydrates, with a total fuel value of 3240 calories." He finds that "children of from 2 to 5 years of age eat about four tenths of this amount, and those between 6 and 9 eat five tenths of it, while girls and boys of from 10 to 12 years take from six tenths to nine tenths."

Just how much this amount of food would be translated in terms of daily life Miss Hunt has attempted to illustrate roughly by the following day's menu for a child six to nine years of age. Breakfast: orange of medium size; cooked oatmeal, one third cup; milk and cream mixed, one half cup; toast, one slice; butter, one half cubic inch; milk to drink, one glass. Dinner: white fish, three ounces as purchased, or one and one half edible portion; potato, one small; celery, cooked in milk, three

<sup>1</sup> The calory, the standard unit of heat energy, is the amount of energy required to raise the temperature of one kilogram of water one degree centigrade.

eighths cupful; bread, one slice; butter for bread and potato, one cubic inch; rice pudding, one half cupful. Supper: egg; toast, one slice; butter, one half cubic inch; milk, one glass; prunes, three, cooked with one half level tablespoon of sugar; cookies.

Children, of course, need food not merely to supply the necessary bodily heat and the energy expended in muscular exercise, but also to supply the needs of growth. Nitrogen is an essential condition for the repair and building up of new tissue; hence a certain amount of nitrogenous food or protein is necessary. Probably, however, even a growing child does not need a high protein diet. While it is well for children of school age to eat meat, fish, eggs, and the like, there is little danger, with an abundant supply of milk and a variety of food, that a child will not have protein enough. It is necessary, however, that a child should have plenty of bread, cereals, fruit, and vegetables every day. It is well to keep in mind nature's lesson in regard to the relation of protein to growth. It is a well-established fact that children nursed by their own mothers thrive best. During the first year of life such children grow at a very rapid rate, usually doubling their weight long before the first year is completed. This astonishing growth is accomplished with a remarkably small amount of protein; for recent analyses show that human milk contains only about 1.5 per cent of albumin, far less than that of most other mammals, less than half that in cow's milk. It is not a question of the amount of protein eaten, but rather of what is digested and assimilated. The total amount of protein given in the above estimates is quite ample. As regards fat and carbohydrates, it is not necessary to have the exact quantities mentioned. If a sufficient total amount is provided, the proportion of the two kinds of food may be left largely to taste. And in general it should be remembered that the standards given are merely estimates based upon our present scientific knowledge. No rigorous norms have as yet been established.

Atwater's two general rules should be printed in italics for all that have to do with the diet of school children: (1) "to choose the foods that 'agree' with them, and to avoid those which they cannot digest and assimilate without harm; (2) to use such sorts and quantities of foods as will supply the kinds and amounts of nutrients needed by the body, and yet to avoid burdening it with superfluous material to be disposed of at the cost of health and strength."

Keeping in mind these elementary facts, the following hygienic principles should be emphasized: (1) It is desirable that children of school age should have a variety of food. It is usually better for them to eat eggs, milk, fish, meat, fruit, vegetables, cereals, and the like, than to be restricted in their diet to a few articles. (2) There should be the greatest cleanliness

in all food for children. This is of fundamental importance. Infant morbidity and mortality would be enormously decreased, as shown by recent studies, if it were possible to supply children with clean milk. Among children of school age, also, a vast amount of disease would be averted if cleanliness could be made universal. This is a very difficult task; for even if the food be clean, children are apt to have dirty hands; and the fruit vender, the grocery man, and the confectioner are often far from cleanly in their habits, and many temptations are in the way of children. (3) Children should, as a rule, be given food that they like. Modern studies by Pavloff and others show that digestion waits on appetite, that the liking of food stimulates the flow of the gastric juices and aids digestion. The custom of some parents in insisting that their children shall eat great quantities of potatoes, oatmeal, and the like, — things eaten sometimes with disgust, — as a condition of having something that they desire, is usually wrong; and it not infrequently happens that a child has some idiosyncrasy, or the like, which makes a certain kind of food indigestible, and sometimes distinctly poisonous. Even eggs and milk are repugnant or poisonous to some children. (4) Children should be trained to take time for eating and to chew their food properly. Habits of health in this respect should be insisted upon, but they can be developed only by long and careful training. The importance of sound teeth and of dental hygiene for school children can hardly be emphasized too strongly, and suitable nutrition of school children demands training in chewing food and in care of the teeth. (See *TEETH, HYGIENE OF.*) (5) The food for school children, especially starchy foods, cereals, potatoes, and other vegetables, should be thoroughly cooked.

If the food for children is clean, thoroughly cooked, what they like, and properly chewed, there is little danger of indigestion; but a few words of warning should be emphasized. Stimulating food and drinks, especially alcoholic drinks, should be forbidden. Tea and coffee, which are extensively used by school children, should be prohibited; also rich and highly spiced food, stimulating meat sauces, pastry, greasy foods, fried potatoes and other products of the frying pan, and uncooked or partially cooked starch, whether in pies, gravies, or elsewhere, should be avoided. Since the school child is devoting much of his energy to mental work, he should not be given food difficult of digestion; and, finally, parents should beware of the innumerable fads that are prevalent everywhere in regard to food. Almost every article on our tables has been tabooed by some one; and on the other hand, almost every form of diet has been recommended as a panacea by some cult or individual. Beset by the claims of innumerable breakfast foods, the doctrines of special cults, which advocate exclusively

vegetable food or raw food, nuts, fruit, particular cereals, or special predigested foods, or the like, it is wise for the mothers of school children to select a variety of simple foods, and beware on the one hand of those who advocate a given diet merely because it is nutritious, and on the other those who advocate special foods because they are easily digested.

**School Lunches.**— This is a subject of great theoretical as well as practical importance. The movement for school lunches is typical of a number of hygienic measures that are likely to be opposed by the argument that they represent a socialistic tendency, that they have a pauperizing influence, that they encroach upon the duties and the responsibilities of the home. It is pointed out that it is not the function of the school to feed children, but to educate them. Any form of medical inspection or physical care that goes beyond the mere detection of contagious diseases — which would directly interfere with the special function of the school — is, it is maintained, an unjustifiable and unwise encroachment on the functions and duties of the home. On the other hand, it is argued that good reason can be given for providing school lunches on the ground that the failure to do so does directly interfere with the special function of the school. The argument is also made from a broader point of view. In providing school lunches or medical inspection, or the like, the school is not taking a new and revolutionary step. A revolutionary step was taken when public schools were first provided at state expense. The very same arguments now used against making the school in part responsible for the physical health of children were used by Herbert Spencer and others against the innovation of providing state education. That was the serious new step; it may have been a dangerous one. It is believed that it was wise; and in accordance with this belief it is obviously necessary and consistent to provide the conditions necessary for the efficient performance of the special function of the school. The conditions in the schoolhouse, for example, must be made suitable for the work to be done in it; and it is no more socialistic, it may be argued, to provide the proper internal heat by supplying pupils with suitable food than it is to provide suitable external heat by warming the school-room. In fact, the great innovation of providing public education having once been made, there is no logical stopping place short of providing every necessary condition for school work so far as it seems expedient for the public to assume the given functions.

Custom has, however, made the home primarily responsible for the physical welfare of children. The school should assume this function only when it is necessary to supplement the care of the home. In many cases this does become expedient and necessary. The furnishing of school lunches in many places is a

case in point. In large cities it is frequently difficult and sometimes impossible for the home to provide properly for the feeding of school children. To say nothing of the poor and the ignorant, even children from the homes of the well-to-do frequently have no suitable midday lunch at home; the parents being away at work, or ill, or overworked cannot prepare it.

The problem, then, is to provide suitable food as a necessary condition of efficient school work, and at the same time to avoid weakening the responsibility of the home, pauperizing the poor, or in any way developing thriftless habits. This problem has with much promise of ultimate success been temporarily solved by the plan adopted in New York and several other large cities of providing school lunches at cost. It has been found possible to provide a wholesome lunch for a few cents, and by cooperation with the homes the small amount of money necessary for buying the lunch can usually be given to the children; and where this has not been possible, it has been found feasible to provide meal tickets by charity and privately without the knowledge of the other children.

The experiments already tried with this plan of furnishing school lunches at cost seem to indicate the feasibility of it for American conditions. In Indianapolis under the efficient management of Miss Carman, in Philadelphia under the direction of Miss Boughton, and in New York under Miss Kittredge and others, it has proved successful. Similar experiments have been tried in many cities in different parts of the country. The price usually charged is from one cent to three cents; and in Philadelphia, where the menus are planned by an expert dietician, one cent buys at least 100 calories of food value. The food usually consists of soup, sandwiches, milk, fruit, cocoa, hominy, shredded wheat with fruit, graham wafers, rice pudding, cereals, and the like.

No question of this kind can be divorced from the educational problems of the school. The training of the school is quite as important as the instruction given, and a twofold opportunity for training is furnished by the occasion for school lunches. First, there is an excellent opportunity for developing healthful habits. Here children can be naturally taught the care of the teeth, the habit of chewing the food, the danger from flies, cleanliness in regard to food; and the habit of eating a variety of wholesome food can be developed, while in addition a certain amount of instruction in regard to the hygiene of food can be given. Again, the school lunch furnishes an admirable opportunity for a certain amount of social training and the development of the spirit of cooperation. Kerschensteiner's principle of a community of workers, an *Arbeitsgemeinschaft*, can easily be adopted in connection with the serving of the lunch. This incidental training in habits of health and

coöperation may be quite as important as any of the instruction given in the school.

In the large cities in this country it is absolutely necessary to furnish school lunches. Thousands of children come to school without suitable food. It is estimated that 35 per cent of the school children in New York City suffer chronically from lack of food. Usually the children have pennies given to them to spend, which without the school lunch they are likely to squander for candy, pickles, or other unwholesome wares from street vendors, while with the school lunch they are taught to spend them for much-needed nourishment. To furnish school lunches at cost is no more socialistic than to provide a college commons or a municipal water supply. If in some cases it does become necessary to encroach upon the rights and duties of the home, it should be done in such a way that it will not be permanently necessary. The school children of to-day are to become the parents of to-morrow; and the school should perform this function in such a way that at least in another generation it will not be necessary.

In many European countries school lunches have been provided for many years. In Norway they are provided free and paid for out of the taxes. In France they are served at cost or free to those who cannot pay. W. H. B.

**England.**—The feeding of necessitous children was for a long time undertaken by voluntary associations out of voluntary contributions. Thus meals were provided in Manchester Board Schools in 1879, and in London such work was organized by voluntary associations in Board Schools, but not through official machinery. After the 1902 Act the provision of meals was left to a Joint Committee on Underfed Children, including representatives of the Council and Education Committee, managers, and two supply associations. In Manchester meals were given in 1903 to children in non-provided or voluntary schools, as well as in Council Schools; and in 1904-05 a charge was made for meals, except in the case of necessitous children. In 1905 the Relief (School Children) Order put the responsibility of feeding children on the Poor Law Guardians, but in the next year by the Education (Provision of Meals) Act (1906) the local authorities were permitted to associate themselves with any committee to provide meals for children, under the title School Canteen Committee; financial aid could be given by local authorities for land, buildings, furniture, and officers necessary for the preparation and service of meals, and where it is found that children are not profiting from their school work through want of food, and funds other than public are not available for the provision of food, the education authority may defray the cost of food out of the rates up to a half-penny in the pound. Many authorities availed themselves of this act, and meals are provided

free to children whose home circumstances after inquiry warrant such a course, while others are given meals on payment of a small fee. As a general rule, centers have been established for the preparation and distribution of food, as at Manchester and Bradford, or, as in London, a contract has been let out to caterers. In the early days, the meals were provided in the schoolrooms, and in many cases teachers gave their help voluntarily; but this has been found unsatisfactory, and in Manchester and other places central locations have been provided for the children. In London the provision of meals since 1908-09 is under the supervision of a Children's Care (Central) Sub-Committee, as the Canteen Committee under the Education (Provision of Meals) Act. Further local care committees are appointed for each school, which look after the general well-being of the children as well as the provision of meals; there is also a local Association of Care Committees which serves to coördinate the work of the care committees, and in time will form a valuable part of the machinery for dealing with children. In 1908-1909, 166,766 meals were provided in London at 697 schools to 39,632 children.

**FOOTBALL.**—The origin of this game is not definitely known. The Greeks and Romans played a game which consisted in kicking a ball

according to certain rules; but it was in England that football was developed. There are occasional references to the game in English history from the twelfth to the seventeenth centuries, when its development was checked temporarily by opposition from the Puritans. Up to that time football was a simple and rough game, played mostly by adult men in towns and villages. The game was revived in the early part of the nineteenth century by the boys in the great public schools of England. The boys at Rugby, Harrow, and Eton adopted a running and tackling game, which after a century of modification and development exists to-day as English Rugby Football and American Intercollegiate Football. At Charterhouse and Westminster the boys adopted a kicking and "dribbling" game, which after considerable modification exists to-day under the name of Association or Soccer Football. Various games of football very similar to English Rugby and soccer have been developed. The best known of these are Canadian football, which is a variation of English Rugby; Gaelic and Australian football, which are variations of English soccer.

The history of football in the United States presents three distinct phases. The first phase covers the early days of New England, when the men on Thanksgiving Day amused themselves by kicking an inflated pig's bladder about the back yards of their houses. The second phase covers the years from 1840 to about 1860, when the Yale freshmen and sophomores had an annual football game with "a round ball inclosed in a leather bag." These matches were more like our modern class rushes than a real game; there was so much fighting and rioting that the faculty abolished these annual matches. The last phase begins about 1870, when Mr. D. S. Schaff, formerly of Rugby School, entered Yale College, where he introduced the game of English Rugby football. Other colleges took up the game, and in October, 1873, a convention was held at New York between Columbia, Princeton, Rutgers, and Yale, and a set of rules was adopted. The English and Canadian forms of the game were introduced in many colleges, but in a few years a distinctly American game of football was evolved. The chief characteristics of the American game are: first, the number of players is reduced from fifteen to eleven; second, each player is assigned a particular position with definite duties in offense and defense; third, running with the ball, interference for the runner, tackling, and kicking constitute the main points in the game.

Since 1873, when football was introduced in American colleges, it has been the most popular sport among students, and match games in this sport have attracted larger attendances than contests in other sports. In American colleges the profits from gate receipts in football are sufficient to pay the deficits of

ten or fifteen other sports. The following financial report of the Harvard Athletic Association is typical of the situation in most American colleges, except that all the figures are proportionally larger.

## FINANCIAL REPORT FOR YEAR 1909-1910

Receipts from Varsity football . . . . .	\$88,387.48
Expenses for Varsity football . . . . .	31,078.81
Profits from Varsity football . . . . .	57,308.67
Expenses for 24 other athletic teams . . . . .	58,981.81
Receipts from these athletic teams . . . . .	40,386.75
Deficit from these other teams . . . . .	18,595.06

This wonderful popularity of football has been achieved in spite of bitter and persistent opposition. About ten years after the introduction of the game in American colleges, President Eliot of Harvard, in his annual report to the overseers for 1884-1885, says in substance: "In the fall of 1883 the committee on athletic sports decided that football ought not to be played, but as the Intercollegiate Football Association was to reform the game by very stringent rules, they waited until they had seen the rules under the new game. After attending four of the principal games, they reported to the Harvard faculty that 'after deliberate investigation they had become convinced that the game of football as at present played by college teams is brutal, demoralizing to players and to spectators, and extremely dangerous.'" The faculty accordingly prohibited intercollegiate contests in football for 1885. The game was soon restored at Harvard, and continued to grow in favor in colleges and schools all over the country. The critics of the game were never silent; they advocated reform or prohibition of football in college faculties, teachers' meetings, newspapers, and magazines. This condition of affairs continued for twenty years. During that time football gained enormously in popularity with students as well as the general public; but this popularity led to the placing of undue emphasis upon victory, and the inordinate desire for victory, in turn, brought forth many evils such as brutality in play, deceit, trickery, extravagant expenditures, etc.

The season of 1905 marks another epoch in the history of American football. Several influential newspapers had carried on a bitter campaign against the game; President Eliot of Harvard had censured the game in each of his annual reports for a number of years; President Butler had prohibited intercollegiate football at Columbia University after the season of 1905; several minor colleges and many secondary schools had followed the example of Columbia; and a student of Union College had been killed in a football match with New York University. Public opinion was aroused, and representatives from many colleges met to discuss the football situation and take measures to reform or abolish the game. The discussions soon revealed the fact that the great

majority of delegates believed in reforming football, and were opposed to any proposition to prohibit the game. The delegates organized the Interscholastic Athletic Association of the United States (see ATHLETICS, EDUCATIONAL), which gained the confidence of educational administrators, and proceeded to reform the rules governing the game of football, to provide competent referees and umpires for match games, and to carry on a campaign of education for a clean, wholesome game. The results obtained were such that nearly all colleges and schools which had abolished football at the end of the season of 1905 reinstated the game in 1906, and the demands for institutional and state legislation against football were no longer heard. The season of 1909 was marred by an unusual number of fatal accidents. The prohibition of football became again a live question; but again the Interscholastic Athletic Association succeeded in restoring confidence in football by making an earnest effort to modify the rules of the game in a way to eliminate, as far as possible, the danger of physical injury to the players. The main change made was to modify mass plays, in which the weight and momentum of several players is directed against one or two players, and to encourage an open game with more running and kicking. The season of 1910 showed that the reforms aimed at by the new rules were in a large measure successful. The number of serious accidents has greatly decreased, and the game is more interesting to the players and spectators.

Under the present rules the game of football is played on a field 330 feet long and 160 feet wide. The field is inclosed by a white border line, and whenever the ball goes outside of this boundary, the play ceases until it is returned into the inclosure. There are also transverse lines to assist the officials in measuring the movements of the ball. There is a goal at the middle of the line at each end of the field; it consists of two upright posts exceeding twenty feet in height and placed eighteen feet six inches apart, with a crossbar ten feet from the ground. The ball is an inflated rubber bladder inclosed within an oval cover of pigskin. The game is played by two teams of eleven men each. Each team is made up of a rush line of seven players,—a center, two guards, two tackles, and two ends,—and four backs, a quarter-back, two half-backs, and a full-back. The object in the game is to advance the ball from the center of the field, where it is put in play, until it can be touched to the ground beyond the boundary line at the end of the field. This is called a "touch-down," and counts five points. After a touch-down has been scored, the team making it has the privilege of trying a kick from placement from any point on a line at right angles to the goal line where the touch-down was made. If the ball is

posts or their projection, it counts one point more. A goal may be kicked by a team in possession of the ball, either by a drop kick or a kick from placement; such a goal counts three points. The only other method of scoring is by a "safety." This is accomplished when a player, having received the ball from a player of his own side, touches it down behind his own goal line. This counts two points against the side making it.

The game begins with the kick-off, the captains having previously tossed a coin to determine the choice of goals. The team which kicks off lines up on the line in the center of the field; their opponents distribute themselves in the territory between their goal line and a line ten yards from the center of the field. The ball is kicked, and the player who catches it attempts to run it back until tackled by a player on the other side. The center-rush then takes the ball, and the teams line up; the quarter-back gives a signal and the center passes the ball back to the quarter-back, who may run with it, but more frequently gives it to one of the half-backs or the full-back to carry it through the line or around the ends. The remainder of the players block their opponents in any effort they may make to reach the runner. The players who run in front and alongside of the player carrying the ball are called interferers, or the interference. According to the present rules a team must advance the ball at least ten yards in three scrimmages or "downs"; if the distance is not gained, the ball is lost and goes to the other side. When a team gains little or nothing in the first two downs, it is customary to kick the ball on the third down, thus losing the ball to the opponents as near their goal as possible.

The most characteristic feature of American football is the advantage in having possession of the ball. This advantage is largely responsible for the roughness of the game because it makes it safer to carry the ball than to pass it or kick it. Consequently, most of the playing consists of bodily contact between the man running with the ball and his interferers on one side and the defensive players on the other side. In English Rugby and soccer the ball is free most of the time, and the players play for the ball instead of the runner, thus involving far less bodily contact than in American football. The attempts made in recent years to lessen the danger of physical injury in football were directed mainly to changing the emphasis from carrying the ball to passing and kicking it.

The game has been made safer than it was, and undoubtedly will be improved still further, but the danger of physical injury cannot be eliminated entirely. The most valuable elements of football would be sacrificed if the game were so modified as to make it as safe as golf or tennis (see ATHLETICS, EDUCATIONAL, for both the value and evils of football). Football is an

admirable form of all-round developing exercise, involving, as it does, running, jumping, dodging, pushing, and struggling up and down the field. It develops strength, speed, endurance, agility, quick perception, and rapid decision, in a larger measure than any other sport. The moral qualities developed through participation in football are no less valuable. The many evils that have been associated with the game of football are not inherent in the game; they are all susceptible to elimination, if those in charge of our educational institutions will accept the responsibility which rests upon them for proper supervision. American football under favorable conditions is one of the most valuable agents for the all-round physical, moral, and social development of American boys and young men. G. L. M.

**FORBES, PATRICK** (1564-1635). — Bishop of Aberdeen; next to Bishop Elphinstone, the founder of the university, the greatest benefactor to education that the Northern University has ever had. He was educated at Glasgow and St. Andrews under his relative, Andrew Melville (*q.v.*), and also at Oxford. He intended to settle on the family estate of Corse, but he showed such aptitude for the ministerial office that he was persuaded to be ordained minister of Keith (1612), although he was then in his forty-seventh year. Six years afterwards (May 17, 1618) he was consecrated Bishop of Aberdeen. It was then that he found his opportunity for proving his administrative abilities as an educationalist. In virtue of his position, he was also chancellor of the university, and he had supreme control in choosing and admitting professors, in disposing of the revenue and directing the studies. He found the condition of the two colleges, King's and Marischal, in a deplorable state. The buildings were falling into ruins, the income was being squandered, and several professorships had fallen into disuse. Even the professors who remained performed their duties in a most perfunctory manner. He set himself at once to have all this remedied. He restored the professorship of divinity in King's College, and founded its salary out of his own private purse. He also instituted a similar chair in Marischal College. He revived an old statute by which regents and teachers of philosophy who had studied under the primarius professor of theology were obliged, after six years, to leave the university

and take charges, and so give place to others. By this means he supplied the parishes with learned clergy, the University with distinguished professors, and the city of Aberdeen with the most famous theologians of the day, who gained a world-wide reputation as "The Aberdeen Doctors." D. M.

**FOREST PARK UNIVERSITY, ST. LOUIS, MO.** — An institution for the higher education of women, established in 1861. Preparatory, collegiate, and musical courses are offered. Four years of high school work are required for entrance to the college, which offers the degrees of A.B. and B.S. There are twenty-nine members on the faculty.

**FORESTRY EDUCATION.** — Forestry, like agriculture, is preëminently an applied science, and therefore its practice is conditioned by the economic needs of the time. While the science of forestry is well developed and rests on a solid foundation of natural sciences, its practical application varies in the different countries in accordance with their economic and political development, and the organization and the scope of the forest schools in the different countries accordingly vary in many essential points.

A long and gradual process separates the present high state of forest science from the few empirical rules which were the entire equipment of the early foresters; the high scientific training of the present-day foresters, which places them at the head of such universities as Giessen, Munich, and Tübingen from that of their prototype "huntsmen," the *Jäger*, whose chief concern was with the chase, the training of dogs and horses, and the setting of traps, and shooting, etc., but who, nevertheless, through the exercise of their calling were brought into contact with the forest in such a

way as to interest them in its care and preservation.

The progress of forestry and forest education has been dictated by the needs of the time. As long as there was an abundance of forest land, timber was hardly recognized as being of sufficient value to be worth claiming as personal property. There was no need at that time for preserving the forest or prohibiting cutting. On the contrary, the presence of the forest in many cases was a hindrance to the development of agriculture, and therefore owners of woodlands encouraged the clearing of the land by any one who desired to settle on it. This is characteristic of the early history of practically every nation, and is still taking place in the newly settled countries. At such a period the returns from hunting and trapping had a greater value than those from the timber itself. Gradually, as the countries of the Old World became more densely populated, and the forests began to show signs of exhaustion, there arose a need for the care of the woodlands, for the timber they produced, and with that, a demand for men capable of handling them. At first this increase in value of the forests showed itself in a stricter legal definition of the property rights of forest owners, in restriction of forest use, and protection against fire and grazing. In middle Europe this stage was passed early in the eighteenth century, when the Huntsmen's Guilds, into which early foresters were organized, were gradually compelled to give place to the true foresters, better equipped to meet the forest problems of that day. With economic and industrial development, with increased demand for wood, occasioned by a multiplicity of uses throughout the world, the value of forests constantly increases, and there gradually arises the need, not only for protecting the forest, but also for securing its regrowth, either by natural reproduction or by planting. The science of forestry and forest education had necessarily to keep pace with this economic development, and the demand for wood led inevitably to the development of schools for the training of competent woodsmen. In most of the European countries, the forests are managed on the basis of a perpetual sustained yield, which requires the services of an organized technical force. Thus the training required of foresters is on a par with that required of physicians, engineers, and lawyers, and there is now scarcely a country in the world which has not some kind of a forest school.

The best and most thorough organization of forest education is to be found in Germany and its nearer neighbors. The density of population and the comparative difficulty of securing wood supplies abroad forced the Germans to intensive use of the soil and to care for the forest lands. Hence there arose in that country earlier than anywhere else the need

for competent men to handle forest properties. Forest education as conducted in Germany is of interest, therefore, not only because it has there reached its highest development, but because Germany has gone through all phases of development which other countries already have passed or will pass, and also because Germany has led the way for most countries in the practice of forestry and in the training of foresters.

**Germany.** — The beginning of forest education in Germany dates back to the close of the eighteenth century, when a number of so-called "master schools" came into existence. Until the middle of the eighteenth century the care of forests was in the hands of huntsmen, who as a rule were illiterate, and among whom were those who had extended their knowledge through experience beyond that of the ordinary woods craftsman. By working under these self-styled foresters for two or three years others prepared themselves and received a certificate of their training. The first master school was started in 1764, by V. Zanthier, in Wernigerode, and was later transferred to Ilsenberg, a town in upper Saxony, situated within the precincts of the old Thuringian forest. This school ended with the death of Zanthier in 1778. In 1785 Heinrich Cotta established a similar school, which was followed four years later by one under Georg Hartig. These two men have since been recognized as the two great masters and fathers of modern forestry. Cotta's school was later transferred to Tharandt, in Saxony, and changed into a state institution, known since as the Tharandt Forest Academy. Several other "master schools" were later taken over by the State, and changed into higher or middle schools of learning under the name of academies. In 1770 the University of Berlin began to show the first interest in forestry by establishing a course of lectures in botany and later in forest economy, to which was added a practical course at Tegel under Burgsdorf. This, however, did not last very long; and with the death of Burgsdorf in 1802 the school was discontinued. The teaching of forestry was transferred from the University of Berlin to Eberswalde, where in 1830 the present Eberswalde Forest Academy was established. A little later there was formed a forest department at the University of Giessen, and forest education was taken up also by the universities of Tübingen and Munich (1789).

Germany possesses at present three professional forest institutions of the highest grade, namely, at Eberswalde, near Berlin; Münden, near Cassel; and Tharandt, near Dresden; and besides these, forest departments at the universities of Tübingen, Giessen, and Munich, and at the Polytechnicum at Karlsruhe. There are two distinct types of forest schools in Germany: first, those which are devoted exclusively to the study of forest science and

Forest Rangers at School in the Woods. (Manitou Park, Colorado.)

Forest Measurement. (Brewer, Texas.)

Foresters taking a Tree Analysis. (Callhoun Co., Arkansas.)

its collateral branches, the so-called "forest academies"; second, the university, *allgemeine Hochschule*, a college, or polytechnic institution, with a comprehensive course of study, of which forestry is one of the prominent departments. There are a number of advocates who favor locating forest schools entirely by themselves, and object to the universities for the reasons that they are designed to aid investigations in the abstract rather than in the concrete; that since they are located far away from any forest, the professors are less acquainted with practical forestry, and the students, though more versatile, fail to learn thoroughly the things most essential for their profession, remain strangers to the forest, and do not learn how to question trees. They further believe that in order to be a means of instruction the forest must be a demonstration ground, and should be so situated that it can be visited daily without difficulty or expense; that the university is more a center of general culture, a feature of secondary importance in forest technology; that the university professors of such sciences as botany, chemistry, zoölogy, and geology are out of sympathy with the forester, and are not willing to adapt the courses to the needs of the forest students; that, while universities are rich fountains of knowledge, they do not specialize enough. They hold, on the other hand, that the forest academies keep the practical always in view, and the attainment of knowledge is always combined with experience.

Those favoring the attachment of forest schools to universities point out that liberal education is just as essential in forest training as in any other profession; that most of the universities are surrounded by woods which are suited as means of instruction, and that it is not the extent of a forest which decides its advantage as a demonstration ground, but its variety of trees and modes of treatment and utilization; that the situation of universities near railroads gives them the best facilities for excursions and for full demonstration in the field; and that scientific research and practical work are not antagonistic to each other. These advantages are clearly shown by the fact that universities have produced more eminent writers and thinkers in the field of forestry than "forest academies." These differing views as to the best place for teaching forestry have not yet been reconciled in Germany, and the whole matter is an open question in the United States.

All the schools of higher education in Germany are state institutions, and the applicant for entrance to them must be a graduate either of a classical or real-gymnasium, and before entering the forest school must have spent a short period, from one-half to one year, in the woods, to familiarize himself, under the guidance of a forest officer, with the general features of the business he proposes to en-

gage in, and in this way test his fitness for it. After this experience in the woods, he enters the forest academy, or the forest department of a university, for two and one-half or three years. Upon completion of his course at the forest academy or university, he does not enter at once the government forest service, but must, at his own expense, spend at least two years in studying cultural operations in various districts, during which time he may be temporarily employed at small wages in some scientific or administrative work. He must keep a full diary of his doings and observations, which must be certified to by the district forest manager with whom he stays, and which form a part of his official examination. For nine months during this time he must constantly perform all the duties of a forest ranger in a certain district, and occasionally also certain functions of a forest manager. After these two years of practical work in the woods, he again enters the university for one or two years to study law, unless he has already done so; and only then can he present himself for the final examination for the position of a forester entitled to have charge of a forest district. His examination lasts from eight to ten days, and is based not only on written and oral examinations, but also on the diary kept during his practical work. Thus the training of the forester in Germany takes from six to seven years.

The curriculum of the Tharandt Academy may be cited as an example of the instruction given at the German forest academies. The course covers three years, and includes the following subjects: I. *Pure mathematics and natural sciences.* (a) Differential or integral calculus. (b) Experimental physics. Mechanics. (c) Meteorology. (d) Inorganic experimental chemistry. Organic chemistry. Practical course in chemistry. (e) Mineralogy and petrography. Geology. Practical course in mineralogy and petrography. (f) General botany: (1). Morphology. Taxonomy. (2). Anatomy. Physiology. Practical course in botany. (g) General zoölogy. Practical course in zoölogy. II. *Forestry. Applied mathematics and natural science.* (a) General course in forest sciences. (b) Forest botany. Practical course in forest botany. Plant physiology. (c) Forest zoölogy: (1). Vertebrates. (2). Insects. (d) Forest protection. (e) A course in forest soils and forest sites. (f) Silviculture. (g) Forest utilization. (h) Chemical forest technology. Practical course in chemical forest technology. (i) Course in the construction of forest roads. (k) Land surveying. Preparation of forest maps. (l) Forest mensuration. Forest valuation. Forest finance. (m) Forest organization. Practical course in forest mensuration. (n) Forest administration. (o) Forest policy. (p) History of forestry. III. *Auxiliary sciences.* (a) Political economy. (b) Law.

(c) Agriculture. (d) Hunting. (e) Game and fish culture. (f) Hygiene. Excursions.

In addition to the forest academies and forest departments in universities, there are also several secondary forest academies, such as those at Eisenach, in Saxony, and Aschaffenburg, in Bavaria, and elementary forest schools for the training of rangers and subordinate forest officers who are directly charged with the carrying out of all forest work.

Thus Germany, with a forest area of about 35,000,000 acres, has nine forest schools, not counting the elementary schools for the training of the technical forest force. The efficiency of forest administration and management of the German forests, which form one of the chief sources of revenue to the states, is directly traceable to the maintenance of a high standard of forest education for those who are charged with the direction of the work.

**France.** — The real beginning of forest education was made in 1825, with the establishment at Nancy of a national forest school (*École Nationale Forestière de Nancy*). Before the establishment of this school the government forests were in charge of untrained men. The offices of foresters were given to courtiers as benefices, and became hereditary, no professional knowledge being required. On the whole, the situation was very similar to that which existed in Germany about the middle of the eighteenth century; but in France, on account of the political turmoil during the First Empire, no attention was given to the proper training of foresters, and the scientific management of the forests was not taken up until a somewhat later time than in Germany. The first director of the Nancy forest school was Bernard Lorentz, who received his education in Germany. The early history of the national forest school was influenced by the teachings of German foresters. The school had a hard struggle for recognition, and did not begin to attain the high standing which it now occupies until 1877, when the government forests and the forest school were transferred from the jurisdiction of the Secretary of the Treasury to the Department of Agriculture. With the transfer of the school to the Department of Agriculture it was entirely reorganized, and at present the French national forest school is one of the highest seats of learning, and is equal to the best forest schools of Germany. Only those who graduate from the Agronomic Institute, of Paris, and in exceptional cases also those who complete a full course in the Polytechnicum, are admitted as students to the forest school. The number of students who are allowed to enter every year does not exceed twelve. They cannot be older than twenty-two years, must have no physical defects, and must be fitted for army life. The course covers two years. The students are required to do three years' service in the army, but the two years of academic life are counted as two

years on the term of their military service. Those who graduate from the school enter the military service as officers of subordinate rank, while those who fail must complete their military service in the rank and file. The students live in the school, and must submit to what is practically a military régime. The curriculum is very similar to that of the German schools, except that considerable stress is laid on horseback riding, fencing, gymnastics, shooting, and drill. Since, as a rule, among those who graduate from the Agronomic Institute of Paris there are more than twelve persons who are willing to enter the forest school, the applicants must pass a competitive examination in mathematics and German. In connection with the forest school there is a forest experiment station which serves as a demonstration ground for practical work in forestry. Graduates from this school enter at once the government service, not as independent forest managers, but, at first, at least for a year, under the guidance of an older forest inspector. The Nancy school, being a graduate school, and its students being chosen from the élite of the graduates of that institute, has produced a type of foresters who are highly educated men, many of whom have attained European fame and brought the practice of forestry in France to a high state of development.

Besides the school at Nancy there is also a secondary school at Barres, which aims chiefly to train young men for the subordinate positions in forest administration. One feature, however, of the school is that its graduates may eventually attain the same high position in forest administration as graduates from the school at Nancy. The entrance is through competitive examination. From among those who successfully pass the examination are selected about twenty or twenty-two young men. Those who are admitted to the school are appointed assistant forest guards (*garde auxiliaire*) in the regular forest service, and remain in this capacity until they finish school, a period of two years. After they graduate from the school and have reached the age of twenty-five years, they are appointed as forest guards, and two years later they are promoted to the grade of "brigadier," corresponding to forest ranger in the United States. After studying one more year in the school, and successfully completing the course there, they are eligible to the positions, at first of assistant forest managers, and later of forest managers. Thus the school at Barres offers the same openings as the school at Nancy, though there is a difference in the method of training. While the school at Nancy lays considerable stress on the theoretical education of the students, the school at Barres promotes principally the practical training.

**Austria-Hungary.** — Just as in Germany and France, the training of forest students was begun in this country at first by private enter-

prise. The two largest forest owners in Austria, the Princes Lichtenstein of Bohemia and Schwarzenberg of Moravia established the first forest schools in 1800. In 1805 the state institute near Vienna and another private school in Bohemia came into existence. The state institute was transferred in 1813 to Mariabrunn, and after many modifications in the character of the teaching was changed, in 1867, to an academy with a three years' course. In 1875 it was combined with the agricultural college in Vienna (*Hochschule für Bodenkultur*), opened in 1872, and at present it is the only forest school in Austria which gives a thoroughly scientific forest education. It has a three-year course, and employs seventy-one professors and instructors. During the years from 1875 to 1904, 2600 forest students were in attendance. The curriculum at the Agricultural College at Vienna is the same as in the best German forest schools. In addition to this forest school, there are in Austria several other so-called "middle schools," and about seven lower schools for the education of guards. In this respect Austria occupies a distinct place among the different countries in the excellent organization of these schools for the education of the subordinate technical forest personnel.

**Russia.**—The attempt at forest education in Russia dates back to 1730, when a number of foresters were secured from Germany to take charge of the management of the government forests. They were also intrusted with the education of foresters, each *Forstmeister* having six pupils assigned to him. This arrangement, however, did not prove satisfactory, and since it was feared that a timber shortage might cripple the navy, a course in forestry was instituted in 1800 at the Naval Academy. This was followed by several other schools, one at Zarskoye Selo (near St. Petersburg) in 1803, another at Kozlovsk, in 1805, and a third at St. Petersburg, in 1808. Of all these there remains now only the Forest Institute at St. Petersburg, which has lived through many vicissitudes, and reflects in its organization, character, and scope of teaching all the changes in the forest policy of Russia. In this case, in particular, it may be said that the history of the St. Petersburg Forest Institute is practically the history of forestry in Russia. This forest institute provides a four-year course, has fifteen professors and instructors, and prepares young men for the higher positions in the Russian forest service. In 1860 another high-grade forest school was created at Novo-Alexandria, near Warsaw, known as the Novo-Alexandriysk Institute of Agriculture and Forestry. It also has a four-year course, and has the same object and scope as the St. Petersburg Forest Institute.

In addition to these two independent forest schools, chairs of forestry exist at Petrovsk Rural Academy in Moscow, and in the Riga

Polytechnic Institute, and also in seven secondary schools of rural economy. Russia leads particularly in the training of forest rangers and guards. These schools, of which there are now thirty, are established after the Austrian pattern. The course of study is two years, and consists mainly of practical work, supplemented by a theoretical study of silviculture. In addition, foresters in charge of a district are allowed to train men and have them pass the final examination at these lower schools. The higher education for forestry in Russia resembles very closely that of Germany in the curriculum of its schools and in the high standard of entrance requirements. Only two high-grade forest schools, however, for an area of about 810,000,000 acres of forest land provides, of course, a comparatively small number of technically trained foresters, as contrasted with the seven forest schools in Germany for a forest area of only 35,000,000 acres.

**Finland.**—In Finland a school of forestry was established in 1863 at Evois, but instruction here was occasionally suspended because of an insufficient number of pupils. Recently the school has been extended; and in addition a course of instruction in forestry at Helsingfors is being contemplated. Schools of instruction for forest guards are also provided.

**Italy.**—A high-grade forest school is located at Vallombrosa, situated in the Apennines at an elevation of 900 meters. The forest institute is under the direction of the Department of Agriculture. The institute was created in 1869. The course of study is four years, beginning March 1 and ending Nov. 1. From 1869 to 1903, 300 students have been graduated from this institute. The number of students that can be admitted to the institute is determined each year by the Department of Agriculture, and as a rule it is very limited. Thus, in 1903, there were in all thirty-four students. Only graduates from technical schools or lyceums (*licenza liceale*) are admitted. Since the number of applicants is always greater than the number approved by the Department, only those who have graduated with the highest rank are admitted to the institute. Graduates are appointed as assistant foresters (*Sotto-ispettore aggiunto*), or temporarily as forest rangers (*Brigadier forestale*). The organization of the institute is military. The courses are thorough, and much stress is laid on the basic natural sciences.

**Sweden.**—Forestry is provided for in a State Forest Institute at Stockholm, and two secondary schools, one at Omberg, founded in 1886, and another at Kloben (1900), where a one-year course is given, mainly in practical work preparatory to entrance into the State Forest Institute. The number of students in the institute is limited to twenty-two, and the term lasts two and one-half years.

The school has, besides its director, six professors; in addition to the training of forest officers for higher positions in the forest service, it provides also a less intensive course for the men of the lower technical grades. The government is very liberal in its support of its forest institute, and tuition is free. The graduates from the schools are at once appointed to the regular forest service, and in ten years may attain the position of *jagmastare*. There are seven schools for the training of the subordinate officers, located in forests in different parts of the country, and each with one teacher and one or more assistants. Not only is the tuition free, but a number of the students receive also board and lodging throughout the course, which lasts one year.

**Norway.**—The first foresters in Norway received their education in other countries, at Tharandt Academy, Eberswalde, and also at Stockholm. In 1897 there was established a forest department in the Norwegian Agricultural College at Christiania. Between 1901 and 1907 sixty-two students were graduated from that school. Students are admitted every other year. The course extends over three years. Besides the forest department at the Agricultural College at Christiania, there are also three schools where elementary instruction is given. One of the schools was founded in 1875 at Kongsberg, another in 1880 at Stenkjaer, and still another in 1884 at Elverum. The term of study is nine months, and only twelve pupils, between the ages of eighteen and thirty years, are admitted every year. The course is both theoretical and practical. In addition to these three schools, courses in forestry are also given at two lower agricultural schools, namely, at the Jonsberg Institute (1897) and at Hove (1907).

**England.**—England's need for technically trained foresters first became pressing when the necessity arose for placing the large forests of British India under scientific management. Having no foresters of its own, the government, in 1866, intrusted the organization of the forest service in British India to a German forester, Dietrich Brandis. For the first few years the officers of the Indian forest service were appointed without any special training, the personnel being recruited from the Indian army, and by the appointment of those seemingly qualified for the rough, adventurous life in the jungle, and fond of camp life and sport. It very soon became apparent, however, that if the forests of British India were to be well organized and managed, it was absolutely necessary to insure a regular supply of young foresters who had a thorough training. In 1866 the government had appointed as assistants to Brandis two young German foresters, and in that same year the first competitive examination was held in London for "probationers," who were to be trained, some in Germany and others in France, for two and

one-half years before entering the regular forest service. Such training of prospective foresters for the Indian forest service lasted until 1875 in Germany, and until 1886 in France. In 1885, however, the English government determined to take over the education of its own forest officers, and established a course of forestry at the Imperial College of Engineering at Cooper's Hill in Surrey. In 1905 the training of the foresters was transferred to Oxford University. The course covers a period of three years, of which one year is spent on the Continent. While this course is primarily intended for "probationers" for service in the Indian Forest Department, other members of the university may attend the instruction in forestry. In addition to the training of forest officers for the higher positions in the Indian service, there was felt the need of giving the natives of India who occupied subordinate positions in the service some technical education in forestry. This was finally provided for in 1878 by establishing the Indian Forest School at Dehra Dun, which in 1884 was changed into an Imperial Institute. At this school the course, which extends over a period of two years, is given both in English and in the vernacular, and from among the graduates of this school the subordinate force is recruited.

For the training of foresters for home service, there has existed since 1895 at the University of Edinburgh a course in forestry which was started by private subscription. This course extends over three academic years, of which two and one-third are spent at the university, and leads to the degree of Bachelor of Science in Forestry. During the fourteen years, from 1895 to 1909, fifty-one students have been graduated from the forest department.

A Departmental Committee appointed by the Board of Agriculture and Fisheries in 1902 to inquire into and report upon British forestry presented a unanimous report, in which it urged "the immediate and effective provision for bringing systematized instruction in forestry within reach of owners, foresters, and woodsmen." As a result of this recommendation Great Britain has considerably increased the facilities for instruction in forestry within the last eight years. While before the inquiry by the Departmental Committee there were no organized courses of instruction in forestry other than those given at the Engineering College at Cooper's Hill and the University of Edinburgh, there are now ten centers where forestry is taught, namely, the University of Oxford; the Forest of Dean, where a school of forestry has been established by the Commissioners of His Majesty's Woods and Forests; University College of North Wales, Bangor; Armstrong College, Newcastle-upon-Tyne; University of Cambridge; the Royal Agricultural College, Cirencester; Glasgow and

A Valuation Crew at Work in the Adirondaek Mountains.

Planting Trees in a National Forest Reserve. (Nebraska.)

Summer Camp of the Yale Forestry School at Millford, Pennsylvania

FORESTRY EDUCATION.

West of Scotland Agricultural College; Edinburgh and East of Scotland College of Agriculture; and Aberdeen and North of Scotland College of Agriculture. In addition, mention should be made of the Inverliever Estate in Argyllshire, which has been purchased by the Commissioners of His Majesty's Woods and Forests for the purpose of carrying out an experiment in afforestation on scientific and economic lines, and the Alice Holt Woods, which are now being worked as a demonstration area for the practical study of forestry.

**Canada.** — In 1907 the Ontario government established in its provincial university at Toronto a fully equipped faculty of forestry. The entrance requirements to the department of forestry are made higher than for any other department in the university, namely, honor matriculation in English and mathematics. The University of Toronto offers a four-year course, leading to the degree of Bachelor of Science in Forestry, B.Sc.F., and after three years' work in practice, to the degree of Forest Engineer, F.E. In addition to the four-year course, a six-year course is provided, which includes humanities and greater specialization in sciences, and entitles the graduates from the forestry department also to the degree of Master of Arts. The latter course is intended to produce professional men with a broad liberal education, leaders of the highest type. In 1908 the Province of New Brunswick established a chair of forestry in its university, and during the summer of 1910 another forest school attempting high-grade education was started in the Province of Quebec, under the auspices of the Crown Lands Department of the province, and affiliated with Laval University. Admission is based on a competitive examination. Ten scholarships are provided to make entrance attractive, and there is, in addition, a promise of employment by the government. In addition to these forest departments in connection with universities, farm forestry is taught at the Guelph Agricultural College.

**Other Countries.** — In Denmark the officials in the higher technical grades are trained at the Royal Veterinary and Agricultural College at Copenhagen, which was established in 1869. The course lasts five years, including one and one-half years of practical work. Tuition is free. In Switzerland the forest school is connected with the Polytechnicum at Zurich. In Spain there exists a high-grade school of forestry, *Escuela Especial de Ingenieros de Montes*, from which the Spanish corps of engineers is recruited. This school was instituted in 1835, and is now located in one of the buildings of the Palace of the Escuriel, near Madrid. It has a four-year course, and the preparation is fully equal to any of the German or French schools. In Japan forestry is taught at the University of Tokio. In South Africa there is a forest school at Cape

Town, established by the Government of Cape Colony, for the scientific training of forest officers and for research in South African forestry. The regular course covers a period of two years, preceded by a preliminary scientific course of one year.

**United States.** — The progress of forest education in the United States has been very rapid. While in 1897, with the exception of lectures on dendrology and forest geography as a part of the botanical courses given in a number of land-grant colleges, there were no professional forest schools, to-day there are about twenty distinct forest schools or forest departments, and twenty-five agricultural colleges, polytechnic institutes, or universities give one or more courses in forestry. Moreover, a number of secondary schools include forestry in their curricula. This marvelous growth has been due to the awakening of public opinion, as the need of the proper care and handling of the remaining timberlands became apparent. This movement was brought to a focus chiefly by the activities of the United States Forest Service. In this rapid growth lies both the strength and weakness of forestry education in this country. The strength is shown by the rapidity with which various universities have taken up forestry, since that is a demonstration that forestry is now recognized as a profession, and that there is a place for the professional forest school. Its weakness lies in the danger of overcrowding the profession with poorly trained men, before the science is fully developed.

The progress of forest education in this country has been radically different from that in Europe. In Europe the practice of forestry anteceded the theoretical development of, and education in, forest sciences. In Germany forest practice existed for a century or more before the first forest school was established in 1764. In this country rapid economic development made heavy inroads upon forest resources, — clearing the forest for farm purposes, and the lack of forest protection have created a sudden demand for technically trained foresters, and thus academic training started before forestry was practiced in the woods. For this reason the teaching of forestry in this country is under a handicap, because there is a lack of illustrations of what can be accomplished by the practical application of forest science. The work of the forester in America, therefore, is that of a pioneer who must first lay the foundation upon which the entire structure of future forestry in this country will rest, and the most thorough forest education becomes for this reason essential.

The first professional forest school was established in 1898 at Cornell University, and almost simultaneously with it a private school at Biltmore was opened by Dr. C. A. Schenck. In 1899 the Pinchot family endowed a forest school at Yale University, and in 1903 the

University of Michigan opened a professional department of forestry. This marked the beginning of the era of professional forest schools in this country, which subsequently spread, through the establishment of courses at one after another of the agricultural colleges and universities throughout the country. There are to-day probably from four to five hundred men engaged in work requiring a knowledge of technical forestry, who are mostly graduated from these schools. It was inevitable that in the rapid multiplication of forest schools in this country, started at different educational institutions, there should be a lack of a uniform standard in the equipment, methods, and character of teaching, even of schools which apparently have the same object in view, namely, the training of the higher technical foresters.

The professional forest schools in this country may be divided into four groups: (1) Graduate schools. These offer college graduates a grade of professional training to fit the students for the highest administrative positions in the profession. They usually give a two-year course leading to the degree of Master of Forestry, and require for admission a college training, with the bachelor degree from an institution of standing. (2) Undergraduate schools, organized on coordinate lines with the other departments of the university. Their curriculum covers four years, and some of them provide also for postgraduate work. (3) Ranger schools, devoted principally to the training of young men for the position of forest ranger and woods superintendent. (4) Courses in forestry. A large number of colleges and universities give one or more courses in forestry, which are intended, not for training professional foresters, but merely as a part of general education, or as preparatory to the study of forestry at some professional forest school.

An attempt to set a standard of forest education which will result in standardizing the profession in this country has already been made at a conference of forest schools which was held in Washington at the close of 1909, in which fifteen universities and colleges giving instruction in forestry participated. A committee of five was appointed to consider and report to the conference a scheme for establishing a minimum standard curriculum in forestry. Such standardization of forest education in this country is absolutely indispensable, since the training of foresters is not, as it is abroad, in the hands of the government, but in the hands of universities and colleges, in the majority of cases privately endowed. In the case of graduates entering the Forest Service, the necessary civil service examination acts, in a measure, as a standard for forest education in this country, but such an examination cannot be a true test of thoroughness of preparation, and besides, there are other fields for forest activities outside

of the government service, where a thorough training is absolutely essential for carrying on the work expected from the new profession.

While the education of the higher grade of foresters is amply provided for in the United States, there are hardly any schools intended primarily for the training of forest rangers or woods superintendents. Undergraduate schools of forestry have short winter or summer courses specially intended for the training of forest rangers. There is one school, the Pennsylvania State Forest Academy at Mont Alto, Pa., which aims principally to prepare young men for the position of forest rangers in the state forest service, and comes closer in its organization and character of education to similar schools in Europe. It is a three-year course, and the vacancies are filled by appointment after a competitive examination. The graduates must remain in the state service at least three years after graduation.

In a class by itself because of its organization, methods, and purposes is the Biltmore Forest School, which is a type of the *Forstmeister* school which was common in the early history of forest education in Germany. It has a one-year course, supplemented by six months of practical work. In that school theoretical education in the fundamental sciences occupies a secondary place, and main stress is laid upon familiarizing the student with the practical problems of the woods.

Unlike England, the United States does not train young men especially for the forest service in the Philippines, but the Philippine corps of foresters is recruited from among the graduates of the forest schools in the states. Similar, however, to the Dehra Dun school in British India, a course in forestry is now given at the College of Agriculture in Los Banos, La Laguna Province, for the training of the Filipinos. The course is so arranged that boys who have completed the seventh grade can enter and graduate in four years. The first two years' work is identical with the work of the agricultural college students, including courses in English, mathematics, botany, zoology and entomology. The last two years are devoted to forestry. The school is similar to some of our undergraduate forest schools, and aims to train men for the higher technical positions in the Philippine service.

Below is given a complete list of forest schools arranged according to the character of the course given in them:—

*Graduate Schools.*—Yale University, New Haven, Conn.; Yale Forest School (founded in 1900). University of Michigan, Ann Arbor; Course of Forestry (founded in 1901). Harvard University, Cambridge, Mass.; Division of Forestry, School of Applied Science.

*Undergraduate Schools.*—University of Minnesota, Minneapolis; College of Forestry, University of Washington, Seattle; School of Forestry (established 1907). Colorado Col-

lege, Colorado Springs; School of Forestry (established 1905). Colorado Agricultural College, Fort Collins. University of Georgia, Athens, College of Agriculture; School of Forestry. University of Idaho, Moscow. Purdue University, Lafayette, Ind. Iowa State College, Ames. University of Maine, Orono. Michigan Agricultural College, East Lansing; Forestry course (established 1902). University of Montana, Missoula. University of Nebraska, Lincoln; College of Agriculture. Oregon Agricultural College, Corvallis. Pennsylvania State College, State College, Pa. State College of Washington, Pullman. Biltmore Forest School, which holds a winter session in Germany, a spring session in the Adirondacks and Southern Appalachians, and during the autumn months in the Lake States. Pennsylvania State Forest Academy, Mont Alto.

*Ranger Schools.* — A number of undergraduate schools of forestry have a short winter or summer course especially intended for the training of forest rangers. Several undergraduate schools, while not intended primarily for training rangers, give courses not much above the requirements of a ranger.

*Courses in Forestry.* — Alabama Polytechnic Institute, Auburn; Connecticut Agricultural College, Newark; Delaware College, Newark; Kansas State Agricultural College, Manhattan; University of Illinois, Urbana; Berea College, Berea, Ky.; Maryland Agricultural College, College Park; Massachusetts Agricultural College, Amherst; Mississippi Agricultural and Mechanical College, Agricultural College; University of Missouri, Columbia; University of Nevada, Reno; New Hampshire College, Durham; North Dakota Agricultural College, Fargo; Oklahoma Agricultural and Mechanical College, Stillwater; Rhode Island State College, Kingston; Clemson Agricultural College, Clemson, S.C.; South Dakota State College of Agriculture and Mechanic Arts, Brookings; University of Tennessee, Knoxville; Agricultural College of Utah, Logan; University of Vermont, Burlington; Middlebury College, Middlebury, Vt.; Hampton Normal and Agricultural Institute, Hampton, Va.; West Virginia University, Morgantown; University of Wisconsin, Madison.

*Courses in Secondary Schools.* — Eric Forest School, Duxbury, Mass.; Mount Hermon School, Mount Hermon, Mass.; Smith's Agricultural School, Northampton, Mass.; Crookston School of Agriculture, Crookston, Minn.; North Dakota School of Forestry, Bottineau; Murray State School of Agriculture, Tishomingo, Oklahoma. H. S. G. and R. Z.

**FORGETFULNESS.** — This term may be either the normal negative of retention, or it may become abnormal. Abnormal forgetfulness, or amnesia (*q.v.*), grades into the types of forgetfulness that occur in ordinary fatigue (*q.v.*) and ordinary lapses (*q.v.*). C. H. J.

See MEMORY.

**FORM.** — The term used in English secondary schools for class or subdivision of the school. It was introduced early in the sixteenth century, and is frequently found in the statutes of that century. Six forms were found almost universally in all schools, and this number has remained as the framework of school organization up to the present time. The highest form is always called the *Sixth*. With the increase of pupils and the growth of the schools, further subdivisions became necessary, and upper, lower, and middle forms were introduced, *e.g.* Lower Fourth, Upper Fourth, etc., and further, without changing the general scheme, forms with new names have been interposed between the old forms, *e.g.* some schools have a *Remove*, between the fourth and fifth, a *Shell* between the third and fourth, and some form between the fifth and sixth. Beyond the six forms, however, there is no uniformity in grouping or names.

See GRAMMAR SCHOOLS, ENGLISH; PUBLIC SCHOOLS.

**FORM.** — See MUSICAL TERMS.

**FORM AND CONTENT.** — As already noted (see CONTENT SUBJECTS), there exists a division of studies into form studies (*e.g.* writing as penmanship, spelling, formal grammar, numerical calculations) and content studies, such as literary composition, history, literature, nature study, etc. The division has practical convenience, but from the standpoint of educational principles brings to light a serious dualism and an important problem. In principle both form and content lose when separated from each other; the value of correlation (*q.v.*), as a practical device, consists largely in overcoming or counteracting their divorce. That the *merely* formal tends to be barren and mechanical needs no argument. Conversely, content, without form, tends to be miscellaneous, unorganized, and, consequently, ineffective. The problem thus brought to attention is whether there exists an inherent

connection between form and content, and if so, what is the genuine meaning of each from the standpoint of their organic relation to one another.

The discussion of experience (*q.v.*) indicates that experience has a double aspect; it always involves subject matter, or is an experience of something, and it involves definite tendencies toward change of subject matter, or exhibits a transition. Since different subject matters (whether facts, ideas, or acts) have very different values, the control of the process of change becomes a matter of fundamental importance. It is necessary that experience should not proceed (or change) at haphazard, but that it should maintain its subject matter at a certain level of value, and that there should be growth, progress to the richer and more significant, not retrogression into the trivial and superficial. The more static aspect of experience (its subject matter taken in cross section) may be called its *what*, or content; its dynamic or lengthwise aspect may then be called its *how*, or method of change. When this manner of change is distinguished with reference to the control of matters of further experience, we have the *form* side.

This abstract formulation may be made more definite by calling attention to the fact that the symbols with which reading, writing, arithmetical and algebraic operations, the general laws of science, etc., are concerned, are the instrumentalities by which the ongoing course of human experience is directed. Any method or tool consciously used for some end may be regarded as *form*, while the subject matter which is obtained and improved through its use is *content*. The problem, then, of the proper relation of form and content in education is the problem of dealing with a subject matter of a valuable experience in such a way that a hold upon this class of subject matter will be secured and improved; in other words, so that a method of control of this type of subject matter will grow up. Content must come first, but the contact with content — the way of experiencing it — is defective unless it results in a gain of power to obtain and manage that sort of content when needed.

Even a slight inspection shows that forms, or methods of control, are of two sorts, one more natural, the other more conventional. The formulæ of mathematics, the laws of the natural sciences, the fundamental logical and psychological relations of speech, are of the former sort. The notational system used in mathematics, forms of oral and written address, rules of punctuation, changes in the inflection of words, modes of etiquette, and much of what is termed "polite manners," are of the latter type. With respect to this distinction, it is (1) requisite that pupils should become aware of what is more natural and fixed in distinction from forms that are more arbitrary and variable, while it is also (2) necessary that they should

realize that, though the use of this rather than that form may be conventional, some conventional arrangement is absolutely necessary. In other words, the existence of conventions is not conventional, but necessary. For example, whether a person speaks the English or the French language originally will be more or less arbitrary; but to be able to speak some language is an indispensable condition of social intercourse and of intellectual power, with all that these two things imply for the guidance and enrichment of experience. The same principle holds as to manners; it is more or less arbitrary that respect is shown by tipping the hat, but the existence of some sign of respect and regard for others is a social necessity.

It will be found that educational errors in practice, with respect to the relation of content and form, tend to group themselves between two poles. Either forms are treated as ends in themselves, not as methods of securing and enriching content; or, in reaction against this exaggeration, they are treated as of slight or negligible importance. We may paraphrase what Kant said of a somewhat similar matter: Form without content is empty; content without form is blind. And this applies educationally to the relation of the phases of subjects which are concerned with mastery of symbols and technique to those phases which consist of subject matter inherently significant.

J. D.

**FORM STUDY.** — A special term to designate instruction in space relations. It has long been assumed in the work of elementary instruction that space perception required no special training. Any analysis of space perception (*q.v.*) makes it clear that the ability to recognize space relations is the product of mental development. This is illustrated in a practical educational way by the fact that the interpretation of the solid figures used in the study of geometry cannot be attained by the pupil without some special study of the figures involved. A clear recognition of the form of objects studied in nature study is another illustration of the same type. Form study is one of the explicit aims of instruction in drawing. A gradual realization of the importance of form study appears in the growing tendency to introduce constructive geometry into the lower grades. C. H. J.

See ART IN EDUCATION; ART IN THE SCHOOLS; DESIGN; DRAWING.

**FORMAL AIMS.** — COURSE OF STUDY, THEORY OF; END IN EDUCATION; VALUES, EDUCATIONAL.

**FORMAL DISCIPLINE.** — This expression has been used to indicate the general reaction upon the abilities of a student that is by many supposed to spring from the method of their

study rather than from the content which is learned. We may distinguish, in the first place, between the information and the discipline that we may derive from a subject; and again between the specific discipline, or increased power of dealing with similar material, and the general discipline or increased ability to deal with any sort of material, the treatment of which involves somewhat the same general powers of the mind. Although formal discipline, a discipline derived from the form of the study rather than from its content, may be said to include both specific and general results, it is in connection with the latter especially that educational controversy has arisen.

The idea of a general mental discipline to be derived from the form of specific studies becomes especially prominent at times in the history of education when a well-established curriculum begins to have less content value than it had at the time of its foundation. Under these circumstances the schoolmasters who advocate the studies that are becoming a trifle antiquated naturally reply to the attack of practical men who question the usefulness of their teaching by saying that, although the information they give is of little practical value, the discipline that their subjects affords increases the general ability of their students to deal with any sort of material. The students learn to observe, to analyze, compare, and classify, to imagine and remember, to reason and judge, to will, even to create. They acquire habits of punctuality, of attention, of regularity, of application to work. All these accomplishments are useful, no matter what one tries to do. It is far more useful, the disciplinary argument runs, to possess such general training than merely to have in mind certain specific facts, which must of necessity have a very limited application.

The disciplinary argument has been used, not only to defend the classics or mathematics, but newer subjects as well, such as laboratory science for all. It has been employed to defend prescription, because, even though the content of the prescribed subjects may not be worth while for all, yet their disciplinary effects are conceived to be universally valuable. It has also been employed to defend election, on the ground that it does not matter what one studies, since after all the important thing is how the study is carried on. It is evident, therefore, that the argument from formal discipline has done very little to settle what should be studied. It has instead clouded the issue and prevented a decisive conclusion.

On the other hand, it is clear that, if there are general disciplinary effects, these are relatively of such great importance as to outweigh all others. The telling differences between men and brutes, between men of different races, and between men of the same race turn largely on what may be called intellectual power. Now if any sort of training can be said to improve this

general power to think, such culture possesses the unusual merit of not simply differentiating its possessor from others less fortunate, but also of elevating him above them. Some facts lead naturally to the assumption that general intellectual power can be increased by education. The most striking is the general mental superiority of the educated class. Although there are marked exceptions, it is unquestionably true that the men who have been well trained according to the educational standards of a period show, on the average, greater intellectual grasp in handling its problems. This fact may, however, be very easily explained by the simple supposition that those who take and succeed in mastering this culture are in the beginning possessed of better minds than the average. Thus their later efficiency may be due not to their training, but to their native ability, of the possession of which the getting of an education is only one among many proofs. For example, although college men may, as compared with others, average greater distinction in life, yet this may not be due to their education, but to the mental ability which enabled them to comply with the severe requirements of the course of study. Thus, when we criticize the foundation of the natural tendency to trace the superiority of the educated to their education, we find that, after we subtract the special advantages of prestige and of specific knowledge and discipline, the margin of general superiority that is left to them seems capable of being accounted for by their initial advantage rather than as a product of their culture.

Undoubtedly the strongest support that the idea of formal discipline has received in the past has come from the practically universal belief in certain abstract mental powers or faculties. The psychologist, in analyzing the processes of the mind, naturally classifies them. Many make the grand divisions of knowing, feeling, and willing. All distinguish between perception, memory, and imagination, reasoning, judgment, will, and the emotions. Now at the very outset of this analysis the psychologist encounters a fact which naturally leads to the theory that these are distinct faculties. He finds that there are many kinds of sensation, and that the impression that any given object makes upon us depends upon which sense it affects. The same object impresses us very differently when we look at it and when we touch it. The qualities of sensation spring from the nature of the sense organs quite as much as from the qualities of the object. The excellence in seeing depends not so much upon what is to be seen, but rather on the eye that sees. And just as the power of sensation is dependent upon the sense organ, so the powers of perception, of memory, of reasoning, etc., are naturally supposed to depend upon the inner organs through the activities of which these forms of consciousness are made possible.

The belief in these various faculties does not

of necessity carry with it the conception that they may be generally improved by exercise in specific directions. However, when emphasis is placed on the form of the activity, and when it is assumed that all activities of a certain form depend upon a special inner power that exerts itself equally in connection with whatsoever material, any observed increase in its efficiency in dealing with this or that content will be naturally expected to appear when attention is directed to other content. The older view that mental activity is such an abstract energy functioning independently of the character of the material presented was modified essentially by the Kantian and especially by the Herbartian theory of apperception. (See APPERCEPTION.) According to Herbart, we should think of the process of apperception as the assimilation of new ideas by ideas that have already been apperceived, or incorporated into the living content of the mind. He rejected explicitly the faculty theory, regarding it as valid merely as a description of various phases in the process of assimilation or apperception. Thus we are led to think of the mind, not as made up of perceptive, imaginative, rational and volitional powers, but rather of groups of ideas, each of which determine for us a specific power of perceiving, remembering, judging, or desiring ideas of a similar character.

Modern psychology has done much to justify the Herbartian conception of the mind. It has been found that memory is a somewhat specialized power. Certain persons have a better memory for visual experience, others for auditory experience, etc. Moreover, it is recognized that one's powers of discrimination are a function of what he knows. The microscopist may see with his glass significant structures that to the untrained eye are practically invisible, since the attention cannot single them out. The same expert might show a lamentable lack of ability to note the essential features in the style of dress worn by a woman. We see what we expect to see. So, too, one's memory is so largely dependent upon association that his ability will lie especially in those fields in which he already possesses a rich fund of material with which to associate the new fact. In a sense, one's experience, what he has assimilated and therefore remembers and knows, determines what he shall see and remember, and how he shall judge and will.

Thus the Herbartian "content" theory of mind has, at least in the main, constituted the point of view of modern psychology. Ideas, or at any rate the physiological processes with which specific ideas are associated, are conceived to be the forces in mental activity. Now, while the acceptance of the faculty theory, as was said, does not necessarily involve the acceptance of the idea that there is a general effect from specific training, its rejection does go far toward discrediting such an effect, at least as maintained by the extreme disciplina-

rians. Herbart and the Herbartians have always subordinated discipline to the content of instruction, and either denied the idea of a general formal discipline, or regarded it as properly a mere incident in instruction. However, so far as concerns the course of study, Herbart himself valued so highly on account of their content mathematics and the classics, the defenders of which have made especial use of the disciplinary argument, that his psychology of instruction has not been actively employed to dislodge from the curriculum that which was generally regarded as having principally disciplinary value. When we come to the question of method, on the other hand, his followers have in their development of his steps of instruction and his notions of correlation constantly emphasized the content, and subordinated entirely the form of instruction to its substance. Herbert Spencer, in maintaining that no subject should be taught for its disciplinary effect alone, but that this should be merely incidental, has fallen in with the passive attitude that the followers of Herbart have been wont to assume on this question.

In recent years the issue has again come to the front for various reasons, two of which may be mentioned more specifically. In the first place, the struggle among subjects of study has caused the various arguments advanced for each to be scanned more critically, with the result that the indecisiveness of the argument from formal discipline has become more apparent. Since all subjects seem able to use it equally well, it tends to be abandoned by such as can employ more effective weapons. In the second place, with the rise of psychological experimentation and its application to educational problems, the question of general disciplinary effects has presented itself as one problem of great importance accessible to the new methods. This experimentation has given to the notion of formal discipline the severest blow that it has so far suffered. The experiments bearing on the subject may be organized under the following headings. These are: (1) the effect of training certain muscles and sensory surfaces upon bilaterally symmetrical ones; (2) the effect of special training on the general accuracy and rapidity (*a*) of discriminations or estimates made by the senses, or (*b*) of motor adjustments; or (*c*) of memorizing; (3) the effect of special habits on general behavior.

1. As early as 1858 Volkman found that training the left arm to discriminate touches that are so close as at first to be felt as one improved somewhat, although not equally, the power of the right arm in such discrimination. Experiments reported in *Yale Studies*, Vols. 2, 6, and 7, and in *Monograph Supplement to the Psychological Review*, No. 13, indicate that improvement through training in the grip of one arm, or in its power to lift a weight, or to

strike a target accurately with a foil, or to hit a dot, results in some improvement in the power of the other arm to do the same things.

2. (a) The experiments of Thorndike and Woodworth reported in *Psychological Review*, Vol. VIII, showed that training in discriminating words containing the letters *e* and *s* brought a little improvement in the rapidity of discriminating words containing *i* and *t*, etc., or misspelled words, or the letter *A* in a list of letters. Accuracy was also improved, but to a lesser degree. Training in discriminating English verbs brought a scarcely perceptible increase in the ability to discriminate quickly other parts of speech. Moreover, it produced a tendency toward omitting to note many instances of the word to be marked. The development through practice of the power to estimate by the eye the areas of certain rectangles improved considerably the power to estimate the areas of rectangles that were different either in size or shape, or both. So, too, the power to estimate heavier weights accurately was improved by practice with lighter ones; but training in estimating the length of lines did not invariably result in a gain in power to estimate longer or shorter ones. Coover and Angell report in the *American Journal of Psychology* for 1907 that training in tone discrimination improved the power to discriminate shades of color.

(b) Judd gives an account in the *Educational Review* of June, 1908, of an experiment in motor adjustment. The assistant in the experiment was placed so that he could not see one of his arms. Certain lines were then exposed to his vision momentarily, and he was required to place a pencil held in the concealed hand in the same direction as each line. After test experiments, he was allowed to observe one line more closely. The result was that he came to place the pencil more accurately than at first. When again the test series was exposed, it was found that errors similar to those originally made in the practice line were lessened. Errors of the opposite sort were increased. Moreover, the fuller exposure of one of this second class of erroneously represented lines failed to result in any improvement in the placing of the pencil. Experiments on geometrical illusions show that when by practice an illusion is corrected, the correction of the opposed illusion is interfered with, provided the experimenter is not aware of his corrections and their reasons. When, however, such knowledge exists, the correction is not hindered, but helped, by the practice.

Bergström reported, in the *American Journal of Psychology*, Vol. VI, an experiment in sorting cards. When by practice the speed of sorting had been improved, the experimenter tried interchanging the positions of the piles of the various kinds of cards. The result was slower sorting than in the original trial. Continued practice in interchanging positions, however, facilitated the shifting from one to the

other. This result was also brought out by Münsterberg, who placed two inkwells on his desk, one full, the other empty. Having accustomed himself to the full one in one position, he interchanged them, with the result that the pen was for a time continually thrust into the empty well. In this and similar experiments Münsterberg found that practice in shifting improved the power to change from one habit to the other. Münsterberg's experiment is detailed in *Gedächtnisstudien*, Teil 1, Beiträge, Heft 4.

Bair reported in Monograph Supplement, No. 19, of the *Psychological Review* experiments with a typewriter. By using movable caps for the keys he changed the letter represented by any one at will. Practice in copying lists containing only six distinct letters increased the power to copy lists containing six different letters. In this experiment the change in the letters represented by the keys did much to remove any advantage of familiarity with the machine. Bair also found that practice in repeating the alphabet with the letter *n* spoken after each letter increased the power to repeat it with the letter *r* or the letter *t* thus introduced.

(c) Professor James published in Vol. I of the *Psychological Review* the results of certain experiments on memory. He found that practice in committing to memory certain verses of *Paradise Lost* did not improve his power to memorize other verses. In his case there was a slight loss, owing possibly to fatigue. With other experimenters there was no significant gain or loss. Ebert and Meuman practiced committing to memory nonsense syllables, noting the method of learning them that seemed most economical. They tested the effects upon the power to learn series of other nonsense syllables, letters, words, and lines of poetry or prose. Improvement was noted that in a general way was proportional to the similarity of test material with the practice material. Their results are published in *Archiv für die gesammte Psychologie*, Vol. IV. Dr. Fracker gives in *Psychological Review*, Monograph Supplement, Vol. IX, No. 2, the results of practice in remembering the order of four tones. He found that it improved the power to remember poetry, the order of four shades of gray, of nine tones, of nine shades of gray, of nine geometrical figures, of nine numbers, and of the extent of arm movements. Introspection indicated that the improvement was due to the development and mastery of a scheme of imagery by which the series might be held together. Winch experimented with British school children, reporting his work in Vol. II of the *British Journal of Psychology*. After being tested in power to memorize, a class was divided into two sections of equal ability. One was given practice in committing to memory 100 lines of poetry; a second test revealed that as a result of its practice it showed ten per cent more gain in power than the other section.

3. Bagley, in his *Educative Process*, Ch. XIII,

tells of an experiment in which school children were trained to be neat in arithmetic papers. They showed no tendency to improve the neatness of papers written in connection with other subjects.

On comparing the conclusions of these experiments, a substantial unanimity of opinion is apparent. It is agreed that wherever practice in one exercise leads to improvement in another, certain specific elements in both are identical and call forth identical responses which promote success in both exercises. In the case of the bilaterally symmetrical organs, the movements or discriminations tested were identical in character. This and the close physiological connection of the two parts through the nervous system made very extensive transference of acquired power inevitable. From their experiments in observation and estimate, Thorndike and Woodworth note the transference of such powers as spring from (1) "ideas of method or of general utility" acquired through training, such as the knowledge that one has a tendency to overestimate all areas and should make an allowance for it; or (2) "facility with certain elements that appeared in many other complexes," such as increase in the speed of eye movements. Coover and Angell emphasize the gain in power of concentrating attention by eliminating "useless kinesthetic, acoustic and motor accompaniments of recognition." Such distracting elements appear when the strain on attention is severe, and ability to suppress them may, Angell thinks, enhance the power of concentration on a variety of difficult tasks in life. Professor James declares that all general improvement in memory arises from improvement in the methods of memorizing. One may account for his own failure to show transference by supposing that he had already mastered his general method of committing to memory, and that particular improvement was in his case due to methods that could be applied only to the practice material. The school children in the experiment of Winch show the converse case of little experience in memorizing and consequent great improvement in general methods. Ebert and Meuman practically agree with James. They trace the improvement in memorizing shown in their experiments to the gradual discovery by each of what was to him the most efficient method of memorizing, and the gradual elimination of other methods. Fracker finds that the improvement in method is due to "the consistent use of some form of imagery," which serves as a scheme for holding the attention and arranging the material to be remembered.

The identical elements that are thus distinguished may be divided into two groups, those of content and those of form. As examples of content elements we may mention sounds, colors, letters, nonsense syllables, words, objects, kinds of geometrical figures, standards

of measurement, ideas, etc. As one grows familiar with such elements, the power to remember them, to attend to them when they appear in new situations, and to do what they suggest increases. The elements of form may be said to consist of the characteristics that various situations present as problems for the attacking mind. Thus we recognize one situation as a problem of memorizing, where from the nature of the material a particular method of committing to memory may be especially useful. Again, we may recognize the need of particular adjustments of perception, such as eye movements which we have already practiced. All situations demand adjustments of attention, some of which may invariably be necessary, while others may suit especially specific kinds of material.

We observe that elements of form and elements of content are equally specific, equally capable of definition. Moreover, both are capable of generalization; that is, both may appear in a variety of settings. The problem of general training is then quite as much one of discipline in content as it is of discipline in form. A better division of mental discipline would yield two phases, which we may denominate specific discipline and general discipline. Specific discipline consists in the analysis of the specific elements which are found to be decisive in determining certain reactions, and the practice by which the appropriate reaction is made the habitual response to each element thus discriminated. General discipline consists of training in the recognition of these decisive elements in a variety of situations.

The successful transference of any result of practice or experience depends upon both these phases of discipline. The failure to transfer neatness from arithmetic papers to others in Bagley's experiment is, doubtless, due to some lack of efficiency in both respects. The specific discipline failed in attaching the reactions connected with neatness with elements which in any situation were expected to call forth these reactions. The suggestion which in the practice was associated with neatness was not the thought of any exercise to be presented to the inspection of a teacher, but rather that of an arithmetic paper to be presented to a teacher *who insists on neatness*. Very naturally, when any of these factors was absent, the children failed to make the response which was associated with the entire group. Or if, as is likely, we may call the command of the teacher in question the critical suggesting stimulus to put forth the effort desired, then the reason for the lack of transference was that the identical element that provoked the desired reactions was absent from all the test material. No child would be neat unless there were some reason for it, and there was no reason for the effort involved in cases where it was not required. In the second place, the experiment illustrates the lack of any attempt

to secure general discipline. If the children had been trained to be neat not only in arithmetic papers, but also in many others, and if many teachers had conspired to enforce this demand, it would have been much more likely that the children would have recognized in some new paper that they were required to present an occasion for the exercise of the virtue in question. Such general training would add to the effect of any amount of specific drill on neatness in any one connection.

The experiments on the effect of training motor adjustments brought out especially the fact of interference. This Professor Judd calls a form of transference. The effect of practice in one activity may be either to interfere with or to aid success in another. The causes of interference are twofold. The first is the failure to attach the reaction in question to the stimulus which is alone that to which it should constitute the response. The situation is not analyzed into the factors that make this or that response desirable. This difficulty is illustrated in Judd's experiment. Here the assistant does not realize that he is in his practice correcting mistakes in placing the pencil. Much less does he realize the character of the mistakes thus corrected. Hence the response of correction, which is learned in the practice, extends to cases where the opposite response should be applied. The various cases are not distinguished, and since all seem alike, the same correcting reaction is made to each. The second source of interference is found where in a new situation one should make to a certain stimulus a different reaction than the one originally learned. This is illustrated in the experiments of Bergström and Münsterberg. Here the different reactions were arbitrarily fitted to the stimulus. In the practical emergencies of life this form of interference arises because in different conditions the same stimulus should be responded to differently. In such cases one must learn to react according to circumstances. Successful transference depends upon the accurate discrimination of each element in the situation that is critical in reference to the reaction, and either the habit or the mental grasp and judgment that correlates these, and from this complex suggestion initiates the proper response.

From the practical point of view specific discipline resolves itself into the analysis and drill of the schoolroom. It may be said that here the work of our schools is least open to criticism. However, it may well be that the reactions that we wish to have transferred from schoolwork to life are not in the school attached to the same suggestions that should constitute their more universal stimuli in effective conduct. For example, the habit of neatness may be suggested by the merely adventitious suggestions of subject or teacher or schoolroom work, rather than by a sense of the general sort of situation that makes neatness desirable.

But if the school often fails in specific discipline, much more likely is it to fail in that which is general. The habits that it teaches are provoked by suggestions that lie imbedded in a more or less constant set of surroundings. Outside this environment they may not be recognized. The physician who learns his art from a book may well fail to note in the sick-room the specific symptoms to which certain forms of treatment concerning which he has read apply. The strange situation distracts the attention, confuses the analytic power, and the mind fails to single out the specific clues that are associated with the proper therapeutic procedure. Teachers have come to recognize the difficulty, and in a general way the solution proposed is to make the atmosphere of the school resemble as much as possible that of life. When the conditions of learning approximate in nature and variety to those of application, one can be fairly well assured that successful transference will be at the maximum.

In conclusion, it may be said that the analysis and the experiments of psychology have done away with the conception of a vague general improvement associated with mental activity. Disciplinary values, like content values, are specific. They consist in learning the decisive suggestions to action, in associating therewith the proper responses, and in learning to recognize these suggestions in new situations. Thus the school has before it a definite, even though a difficult problem. So far as discipline is concerned, this problem means first the selection of the reactions that have the greatest value, second the determination of what is the true and universal occasion for each reaction, together with modifying or exceptional conditions. Finally, we have the problem of drill and of application, of specific and of general discipline, such as will insure the successful utilization of the habits which the school has elected to teach.

**FORMAL EDUCATION.** — A term applied to any training or education which is given in a direct, conscious, and systematic manner, as opposed to the kind of development which is incidental to life. In this sense what one learns outside of school represents a child's informal or incidental education;

what he gains through tutoring or at school is his formal education. Thus the end of school life is spoken of as the close of the period of formal education. The same fundamental distinction is also applied in the classification of the influences of school life itself. What the pupil gains through the direct and systematic instruction of the classroom, that is, through the study of the subjects of the curriculum, is his formal instruction, as opposed to the incidental influences of school life, which are exerted through the social life, the playground activities, the government and the discipline of the school.

Formal instruction or education, however valuable, needs to be supplemented by many and varied experiences outside the classroom. An individual's complete education is gained through the contacts of his whole life under whatever institutional influences these may be gained. School education is only partial; it fails to provide a complete series of experiences. While it gives much in a thoroughly accurate and systematic form, it frequently fails to give a practical organization to knowledge so that the facts and principles gained are closely associated with actual problems and ordered so as to provide a properly controlled conduct with reference to them. The formal education of schools in particular tends to restrict itself to the intellectual level of consciousness; the sensibilities which evaluate situations and the skilled actions which modify them are too often underemphasized by classroom instruction. Modern educational theory recognizes this truth when it suggests that the complete curriculum of the school consists of all the school activities, whether they occur on playground or in recitation; and modern practice, in line with this belief, encourages supervised play, self-government, and various forms of organized sociability among children. In a similar manner, the influences of home, neighborhood, religious and other modes of institutional life are regarded as distinctly necessary supplements to the school. H. S.

**FORMAL METHODS.** — A process of teaching which follows a more or less artificial order or manner. The *five formal steps of the recitation* constitute a classic instance of a formal procedure in teaching. Many other examples might be cited. Teaching the addition combinations in the order in which they appear in systematic tables rather than in the order of their need is a case in point. Learning to memorize a poem line by line rather than by wholes or thought units is another. Spelling isolated words in lists or columns is a formal mode of procedure, whereas spelling words in the context of meaningful sentences or para-

graphs is a natural method. The use of formal methods in teaching procedure has its value in giving the teacher a larger control of his own teaching technique or of the mental activities of children. Beginners in teaching find it very essential to proceed by given steps so as to avoid diffuseness. And all teachers find it useful to separate the mastery of a subject into steps, in order that specific points of difficulty may be located. Thus the full written expression of the solution of a problem in arithmetic is quite unnatural, as many calculations could be performed mentally, but a full formal statement is valuable in revealing the child's whole activity, and so exposing each weakness requiring correction. Too exclusive a use of formal methods was characteristic of early American teaching. Present-day practice makes a relatively larger use of less formal and therefore more natural methods. H. S.

**FORSTER, WILLIAM EDWARD** (1818–1886). — English educational statesman; was born at Bradpole, Dorset, the only child of William Forster, a devoted and widely traveled minister of the Society of Friends, who died in 1854 in East Tennessee while on a mission urging the abolition of negro slavery, and of Anna, sister of Sir Thomas Fowell Buxton. The penetrating influences of a home life which was at once austere, simple, cultivated, natural, fervent, unflinchingly consistent, and permeated by the practical idealism of the Society of Friends, fixed Forster's character and tone of mind, making him like John Bright, a typical Quaker statesman of the Victorian era. Throughout his life Forster, like Ruskin, was sensitive to the influence of observant and clear-sighted women, and never equally at his ease or in sympathy with the men with whom he had chiefly to act in political affairs. Brought up in a religious society in which men and women had equal influence, he never adjusted himself afterwards to the different standards which prevailed in those wider circles of Eng-

Daniel Defoe (1659 ? -1731).

A GROUP OF ENGLISH EDUCATIONAL LEADERS.

lish life in which the views and interests of men were traditionally paramount. Hence, in his political career, Forster, though universally respected, was constantly moved to an irritation which a more supple character would have concealed, but which his native awkwardness of manner rendered conspicuous. His passion for public affairs, like his father's missionary zeal, was free from any base taint of vanity or self-interest, and sprang from an intense desire to guide public policy by what he believed to be the principles of the Christian faith. But his evangelical ardor for social reform quickly came into conflict with some of the complex forces which were at work in the English political struggle, and the power, or even the existence, of which his early training had not prepared him to foresee.

Educated at home till thirteen, Forster went for five years to Quaker schools in Bristol and Tottenham. In consequence of his father's misgivings as to a political career for his son, the youth was sent into the woolen business, first at Norwich, then at Darlington, and finally, in 1841, at Bradford, Yorkshire, where he joined William Fison, a woolen manufacturer, in a partnership which lasted till death. During his business career at Bradford, Forster was energetic in the study of social questions, and was brought into personal contact with Robert Owen, Thomas Cooper, the Chartist, Frederick Denison Maurice, and John Sterling, and into intimacy with Thomas and Jane Welsh Carlyle. Thus, while still a provincial manufacturer engaged in an anxious business struggle, he was admitted to the circle of those who, on the progressive side, were among the intellectual and moral leaders of national life. In 1850 he married Jane Martha, the eldest daughter of the late Dr. Thomas Arnold of Rugby. Taking, after his marriage, an increasing part in public affairs, he became prominent as an advocate of Parliamentary reform and as an eager champion of the Abolitionist Party in the United States, with whose policy in regard to negro slavery he had inherited from his father and from his mother's family a profound sympathy. In 1861 he was elected Member of Parliament for Bradford, which city he continued to represent till his death in 1886. With Bright and Cobden, he threw the whole of his Parliamentary influence against any attempt to recognize the Confederacy in the American Civil War. In 1865 he first entered office as Under-Secretary for the Colonies in Lord Russell's government, and, from the experience thus gained, became a lifelong advocate of imperial federation, his acceptance of which ideal, in some ways so foreign to Quaker sympathies, may be traceable in part to the influence of the Arnold family tradition. When Mr. Gladstone became Prime Minister, in November, 1868, Forster joined the government as Vice-President of the Committee of Council on Education, but was not then ad-

mitted to the Cabinet, a fact indicating a singular underestimate of the importance of the education bills, the preparation of which, through his place in the government, fell chiefly to him.

Two great measures give Forster a permanent place in the history of English education. In 1869 he conducted the Endowed Schools Bill through the House of Commons. (See for details ENDOWED SCHOOLS ACTS.)

On Feb. 17, 1870, Forster introduced, on behalf of Mr. Gladstone's government, the Elementary Education Bill. (See for details ENGLAND, EDUCATION IX.) It was the outcome of many years of philanthropic agitation, and, in its original form, bore marks of amateurish draftsmanship, combined with prophetic but premature anticipation of the future trend in English local government. It is said that Mr. Gladstone, though Prime Minister, could hardly be induced by his colleagues to give his mind to the details of the problem before the bill was introduced. Forster, though not a member of the Cabinet, bore the brunt of the business. The object of the bill was, in Forster's words, "to complete the voluntary system, to fill up gaps, sparing the public money where it can be done without, procuring as much as we can the assistance of the parents, and welcoming as much as we rightly can the coöperation and aid of those benevolent men who desire to assist their neighbors." In preparing the measure, Forster was greatly helped by his friend, Canon Jackson of Leeds, and showed himself to have inherited the tradition of Sir James Kay-Shuttleworth, who always believed that the progress of English national education would be best furthered by a succession of concordats between the great religious denominations and the State. It is clear that Forster's mind wavered between two different conceptions of public elementary education. Was it to be a great structure of educational discipline regulated by the State with the aid of local authorities, providing the basis for secondary and technical education, and closely related at all points to those other branches of the public service concerned in social welfare? Or was it to be, in the main, an eleemosynary work, conducted in great measure by the churches, maintained partly from the voluntary subscriptions of the benevolent, with the aid of enlarged grants from the State and supplemented by subsidies from local rates, but content with a somewhat low standard of attainment, and shorn of costly ambitions to branch out into secondary and higher education? The bill was a compromise between these two views. Nothing else was possible at the time. The civic ideal in education was still in its infancy. The aid of the religious bodies and of the benevolent subscriber was still indispensable to success, while the opposition of the churches would have been fatal to the Parliamentary

prospects of the measure, if not in the House of Commons certainly in the House of Lords. But Forster's hesitancy between these two ideals lay deep in his political consciousness. On one side he was drawn toward bold state action; on the other side he was attracted by the generosity of the religious bodies and by the varied charities of private benevolence. Probably the hidden cause which produced this hesitation between two conflicting ideals was his profound belief in the necessity of religious influences in national education. He foresaw that any elaborate state organization of schools would inevitably tend to secularization. On the other hand, he perceived that voluntary denominational effort had completely failed to grapple with educational destitution, and must therefore be supplemented by state action, combined with the efforts of local authorities. His speech on the first reading reflects this duality of purpose. It also shows that he had little conception of the inevitable cost of the system of national education which he was introducing. "After all," he said, "it is but a very small matter as regards the rate. An education rate will save the prison rate and the pauper rate. It will not be a special rate, but a charge on the poor rate. But should it exceed 3*d.* in the £1 (and I do not believe it will amount to anything like that sum in the vast majority of cases), then there is a clause in the bill which stipulates that there shall be a very considerable extra grant out of Parliamentary votes."

Throughout the passage of the bill, Forster's personality had great influence upon the course of events. He was profoundly interested in school questions. He was intimate with many of those who had long experience in school administration and in teaching. He stood midway between the advocates of universal public control and the friends of voluntary enterprise. He was a link between the two conflicting ideals. He was a mediator between the two opposing forces in national life. He was a democrat, but not a secularist; an ardent supporter of religious influences in education, but at the same time a believer in the possibility of united Christian teaching, the spirit of which would transcend denominational distinctions. In this last respect the influences of his Quaker up-bringing were clear, just as in his inclination toward state effort in organizing national education upon broadly Christian lines, we can see the influence of the ideals of Dr. Arnold of Rugby.

With the rest of Forster's political career this article is not concerned. It must suffice to say that no more courageous and disinterested Minister ever served in a British government.

**FORT WORTH UNIVERSITY, FORT WORTH, TEX.**—A coeducational institution, chartered in 1881 as the Texas Wesleyan College, the present title being secured in 1889. There are maintained as part of the university a sub-academy, an academy, college of liberal arts, and schools of commerce, pharmacy, and nursing. Students are admitted to the college by certificate or on examination requirements equivalent approximately to fourteen units. Degrees are granted in arts, science, philosophy, literature, and medicine. The college has a faculty of thirty-two.

**FORTUNATUS, VENANTIUS. (HONORIUS CLEMENTIANUS).**—Christian poet; born in Gaul 530 A.D. He studied grammar, rhetoric, and poetry at Ravenna under the best masters. His pilgrimage to the tomb of St. Martin of Tours is described in his principal poem. He lived for some years at the court of Sigebert, King of Austrasia, in honor of whose wedding he composed an epithalamium. Here he acquired great reputation as a poet. Later on he was entertained by Queen Rhadegund at the Abbey of St. Croix, which she had founded at Poitiers, where he continued his literary and philosophical pursuits with ardor. He composed many lives of the Saints, theological treatises, and poems. He wrote many Latin hymns, the most famous of which are the *Vexilla Regis* and *Pange Lingua*. He was the first to use rhymes successfully and to master the trochaic tetrameter. His poetry was the expiring effort of the Latin Muse in Gaul, and he was the last poet of the period preceding Charlemagne. His writings are valuable as pictures of Merovingian society. In the frequent attacks which were made on pagan writings as unsuitable for school use, the works of Fortunatus, particularly his hymns and poems on the Saints, came to hold an important position in the curriculum. Just before his death he became Bishop of Poitiers. (See Wimpfeling, *Isidoreus Germanicus*, ch. 21.)

**FOUNDATION READERS.**—Reading books used in the first year's work in teaching children to read; they usually include a primer and a first reader. They are specially arranged so as to give a simple context well within the experience of the child and expressed in words the sound of which is easily learned by the pupil. These foundation readers aim to give a large power in the ready recognition and pronunciation of new words at

sight. They are usually, though not always, arranged on a phonetic basis. Such basal readers aim to give a fairly thorough mastery of the mechanics of reading, so that subsequent reading may be mainly concerned with the getting of the thought. H. S.

**FOX, GEORGE.** — FRIENDS, EDUCATIONAL INFLUENCE OF SOCIETY OF.

**FOX, WILLIAM JOHNSON (1786-1864).** — An English preacher, politician, and man of letters. He was strongly interested in philanthropy and social reform, and belonged to the Manchester school of thought. On his election to Parliament as member for Oldham in 1847, he took up the question of education, and in 1850 introduced a bill to provide for compulsory secular education. He advocated the establishment of free schools supported by local rates wherever inspectors reported an insufficiency of schools. Teachers were to be appointed, paid, and dismissed by school committees. Where local bodies failed to establish schools, the Committee of Council was to step in. The progress of teachers was to be encouraged by the publication of annual reports by the Committee of Council. Religious education, however, was not to be given in rate-maintained schools, although the State might support denominational schools for success in secular subjects, and arrangements might be made for religious education of children of rate-aided schools at convenient times. Fox supported his bill by a manifesto of London workingmen against sectarianism. He distinguished between education and instruction or acquisition of knowledge, and emphasized

the importance of efficient teachers, no matter how perfect the organization of a school system might be. The bill was rejected by a large majority. In 1851 Fox moved in the House of Commons "that it is expedient to promote the education of the people, in England and Wales, by the establishment of free schools for secular education, to be supported by local rates, and managed by committees elected specially for that purpose by the ratepayers." On this occasion he pointed out that sufficient provision was made for religious education in the fifty-ninth canon, and referred to the anxiety of the opposition for the religious education of children other than their own. The work begun by Fox, who represented the opinion of a large body of people in the north of England, was taken up by Lord John Russell. But it required nearly twenty years more before these views were to be realized.

HOLMAN, H. *English National Education*. (London, 1898.)

**FRACTIONS.** — History of Common Fractions. — In general, it may be said that the ancients avoided fractions almost entirely, and by an expedient that was very ingenious. Assuming a convenient unit of measure, let us say one that corresponds to the modern yard, they then took some convenient unit that was a fractional part of the first one, like the foot, and another that was a fractional part of the second, like the inch, and so on. These smaller units were really fractions of the larger ones, although they were not looked upon in that light. Instead of thinking of 2½ feet, the ancients thought of 2 feet 6 inches, and so for other fractions. Thus arose the system of compound numbers (*q.v.*), which played such an important part in all metrical work from earliest times to the nineteenth century. Just at present we are in a period that will see the decay of compound numbers, these being replaced by the modern device of the decimal fraction mentioned below. With the idea explained above, the Romans, for example, generally divided their units into twelfths, of which we have a relic in the inch and in the ancient ounce. This radix was chosen because it allows its half, thirds, and fourths to be represented as integers, thus covering the most important business fractions.

The arrangement of compound numbers was not sufficient, however, for scientific purposes, and to answer these demands there early came into existence several kinds of fractions, of which two still remain, the common and the sexagesimal fractions. It is difficult to say which of these is the earlier, since the origin of each is lost in the maze of ancient history. It is natural to think that the common fraction

was the first, as is probably the case; but in some respects the sexagesimal is simpler than the ancient common fractions with which we are familiar, and hence may have had a very remote origin. For example, it is simpler to think of 2 hours 23 minutes 17 seconds than of  $2\frac{1397}{3600}$  hr.

The earliest extant work dealing with fractions is the Ahmes (*q.v.*) papyrus, of about 1700 B.C. At this time only unit fractions were recognized, with the single exception of two-thirds, for which there was a special symbol. These unit fractions were commonly indicated by a special symbol, under which the denominator was written. Ahmes, however, recognized the necessity, for purposes of multiplication and division, of having the quotients of 2 by a series of numbers, and so he prepared a table of these quotients expressed in unit fractions. Thus he states that  $2 \div 43 = \frac{1}{42} + \frac{1}{35} + \frac{1}{123} + \frac{1}{371}$  so that he has essentially a table of fractions with the numerator 2. It will be noticed that approximate values of the fraction in question may be obtained by taking the sum of the first  $n$  of the unit fractions. The use of unit fractions extends over a long period. In the Akhmim papyrus (*q.v.*), written upwards of twenty-five hundred years after the original of the Ahmes work, unit fractions are given in essentially the same manner as in the older treatise. In the Middle Ages in Europe such forms were known as simple fractions (*simplices fractiones* in some of the manuscripts), and even as late as 1559 Buteo, a mathematician of some merit, gives the square of  $1162\frac{1}{2}$  as  $1350534 \frac{1}{2} \frac{1}{4}$ . The unit fraction is also found very early in India. In a rule for the approximate quadrature of the circle, perhaps as early as the eighth century B.C., the value of  $\pi$  is given as  $(\frac{7}{8} + \frac{1}{8 \cdot 29} + \frac{1}{8 \cdot 29 \cdot 6} + \frac{1}{8 \cdot 29 \cdot 6 \cdot 8})^2$ , which is equivalent to 3.0881 . . . (See R. C. Dutt, *A History of Civilization in Ancient India*, London, 1893, Vol. I, p. 273.)

In Rome the commercial fractions were referred to the *as*, which was looked upon as one of the principal units. Sixteen *asses* made a *denarius*. A twelfth part of the *as* was the *uncia* (ounce). Hence the Romans had the following scheme based upon unit fractions:—

<i>Multiples of the as</i>		<i>Name</i>
1 <i>as</i>	= $\frac{1}{16}$ <i>denarius</i> = $\frac{1}{2}$ + $\frac{1}{8}$	<i>Denarii semuncia et sicilicus</i>
2 <i>asses</i>	= $\frac{1}{8}$ <i>denarius</i> = $\frac{1}{2}$ + $\frac{1}{4}$	<i>Denarii uncia semuncia</i>
3 <i>asses</i>	= $\frac{3}{16}$ <i>denarius</i> = $\frac{1}{4}$ + $\frac{1}{8}$	<i>Denarii sextans sicilicus</i>
	etc.	etc.

<i>Submultiples of the as</i>	
$\frac{1}{2}$ <i>as</i> = <i>semis</i>	$\frac{1}{5}$ <i>as</i> = <i>clertans</i>
$\frac{1}{3}$ <i>as</i> = <i>tricens</i>	$\frac{1}{2}$ <i>as</i> = <i>uncia</i>
$\frac{1}{4}$ <i>as</i> = <i>quadrans</i>	$\frac{1}{288}$ <i>as</i> = <i>scriptulum</i>
etc.	etc.

Each of these fractions had its symbol, and a list of these symbols as they existed in the early Middle Ages may be seen in the work often attributed to Bede (*q.v.*), *De ratione*

*Unciarum*. (See the Paris edition of his *Opera omnia*, 1862, Tomus I, p. 699.) On coins the half was commonly represented by *S* (for *semis*); the third by four disks, ●●●●, meaning  $\frac{1}{3}$ ; the fourth by three disks, meaning  $\frac{1}{4}$ ; the sixth by two disks, and the twelfth (*uncia*) by one disk. Fractions did not, however, play much part in the mercantile life of the Romans. Varro (116-28 B.C.), in his work on the Latin language, mentions only twelve fractions, while Metianus (fl. second century A.D.) gives only two more. The learned Isidorus of Seville (*q.v.*), in the seventh century, mentions only eight, and five hundred years later Adhelard of Bath (*q.v.*) gives only twenty-four.

Our method of writing common fractions is due essentially to the Hindus, although they did not use the bar. Brahmagupta (*q.v.*), writing in the seventh century, used  $\frac{5}{8}$  for  $\frac{5}{8}$ , and Bhaskara (*q.v.*) did the same. So in the Sanskrit manuscripts generally we find no bar used, even in relatively modern times. The Arabs introduced the bar, but they did not use this form exclusively. The earlier manuscripts often follow the Hindu form, and Rabbi ben Ezra, deriving his knowledge from these earlier writers, also omitted the bar. The Greeks and Romans were, of course, unaware of it, although the former had a very good fraction system. Early Renaissance writers occasionally attempted to combine the Roman numerals with the Arabic forms, as in the case of  $\frac{III}{III}$  and  $\frac{II}{VII}$ , as in the work of Köbel (1518).

Some of the early printed arithmetics omitted the bar entirely (as in the Bamberg arithmetic of 1483), others omitted it in small fractions, while retaining it in large ones (as in Rudolff's work of 1526), and others omitted it in the case of  $\frac{1}{2}$  of  $\frac{2}{3}$  of  $\frac{3}{4}$ , which was written  $\frac{1}{2} \frac{2}{3} \frac{3}{4}$ . Thus Hylles (1600) remarks: "And here you see the first fractions to wit  $\frac{1}{2}$  being a true fraction, written with his lyne as it ought to be — and the other two that is to say  $\frac{2}{3}$  and  $\frac{3}{4}$  — to be written without any lyne as their vse and order is."

The name *fraction* is from the Latin *frangere*, to break. It is, therefore, a broken number, a fragment. The name has not been at all universal. Boethius, following the earlier classical writers, used ratios in his scientific treatment of fractions. He treats of the commercial fraction under the head *De Minutiis*. This use of *minute* for fraction was very common among mediæval writers, not merely in respect to sexagesimal fractions, but also in respect to common fractions. Thus in the twelfth century Adhelard of Bath used *minuciac*, while at about the same time the learned Spanish Jew, Johannes Hispalensis (John of Luna), preferred *fractiones*. At the time of the first printed books, the two names were used interchangeably. Thus Huswirt (1501) says that *Minutia siue fractio nihil*

*aliud est qz. pars integri*, and the popular Gemma Frisius (*q.v.*) speaks of *fractiones, minutias aut partes*. In English, the word "fraction" appears early, Chaucer in his *Astrolabe* (1391) using the form *fraccion*. The Italians made use of another Latin root, *ruptus*, (whence rupture, a break), and derived the word *rotto* (plural *rotti*). Thus Paciolo (*q.v.*), in 1494, used *rotti* generally, but also *fractioni* and *fracti*. From the same root came the early French *roupt*, *rompu*, and *routz*, and the Spanish *roto*. The Germans followed their usual plan of taking Teutonic roots instead of Latin. Grammateus (1518), for example, has a chapter *Von Pruehen*, in which he speaks of *ein iglicher pruch (welcher man in latein fraction nennet)*, and Adam Riese (*q.v.*) speaks of *ein gebrochene zal*. The Dutch followed the German lead and the earlier books have such forms as *die ghebroken ghetalen* (Raets, 1576) and *Ghebroken* (Mots, 1640). The Teutonic custom affected the earlier English writers, so that in two anonymous arithmetics of 1546 and 1574 we find the phrase "in hole numbers or in broken." Similarly Baker (1568) speaks of "fractions or broken numbers," and of a "broken of a broken." Even in the first native American arithmetic (Greenwood, 1729) there is a chapter entitled "Fractions, or Broken Numbers," and the same expression appeared in Pike's well-known arithmetic in editions well into the nineteenth century.

The prefix "common" was originally used to distinguish the fractions from the sexagesimal forms. The medieval Latin expression was *fractiones vulgares*, whence the "vulgar" fractions of the English, an expression that was generally used in the United States until the middle of the nineteenth century. The prefix "common" is not so recent as is sometimes thought, for Digges, as early as 1579, speaks of "the vulgare or common Fractions."

The common definition of "fraction" has been, and is, in substance, one or more equal parts of a unit. The more general definition, as a special indicated division, is a later development, and as an indicated division is still later. Ramus (*q.v.*), for example, says that in dividing a smaller number by a greater one, a quotient exists that is less than unity, and this is a *fractio sive pars*. The fusion of the two ideas, of part and quotient, is relatively recent. (For a discussion, see Bobynin, in the *Bibliotheca Mathematica*, Vol. XIII, 2, p. 181.)

The names of the terms have undergone considerable change. The medieval Latin names for numberer (*numerator*) and namer (*denominator*) came into common use after the Arab fractions became generally known, and particularly among scholars in the fifteenth century. Since they were found in the early printed Latin arithmetics, they were generally adopted by the Latin races. The Teutonic languages, however, generally translated these terms, and they appear in the early German

as Zeler and *Nenner* (as in Stifel's *Deutsche Arithmetik* of 1545), and in the early Dutch as *teller* and *noemer* (as in the work of Petrus of 1567) or *Telder* and *Nommer* (as in the work of Raets, 1576). In English an attempt was made to depart from the Latin form, as when Hylles (1600) wrote: "Numerator which also for more shortnesse is sometimes called the Topterme or top only: and that the lower term is vsually called the Denominator or Base." A similar use of top and base is found in the well-known Latin arithmetic of Gemma Frisius (1540), where *superiori* and *inferiori* are also used. It is to be hoped that some shorter names than numerator and denominator may some time come into general use, but possibly the decay of the common fraction (save in very simple cases) will render this unnecessary.

The reduction of fractions to lowest terms was a problem of considerable difficulty before the invention of the decimal fraction. Thus so good a writer as Clavius (*q.v.*) used the fractions  $\frac{109}{141}$  and  $\frac{2432500}{141}$  in examples that were of a practical nature. In order to reduce such fractions to lowest terms, for the purpose of operating with them, it was necessary to find the greatest common divisor (*q.v.*) of the two terms by the long division method, and hence the presence of this topic in the older arithmetics.

The sequence of operations in fractions has generally been regulated by analogy to the sequence in treating integers, beginning with addition. Not infrequently, however, the sixteenth-century writers followed the more psychological plan of beginning with the multiplication of fractions. Thus Robert Recorde (*q.v.*), who wrote his *Ground of Arts* about 1540, says: "There is an other ordre to be folowed in fractions then there was in whole numbres, for in whole numbres this was the ordre, Numeration, Addition, Subtraction, Multiplication, Diuision and Reduction, but in fractions (to folowe the same aptnesse in proceeding from the easiest woorkes to the harder) we muste vse this ordre of the woorkes, Numeration, Multiplication, Diuision, Reduction, Addition, and Subtractiō" (1558 edition, folio R iii, v.). Of late we have returned to the suggestion of not beginning with addition, and all primary arithmetics to-day show how to take a fraction of a fraction before adding two or more fractions. Of the operations, the most difficult to explain is division. The old method was to reduce the fractions to a common denominator and then divide the numerators, and this is the plan occasionally pursued in teaching beginners to-day. The Hindus knew the process of multiplying by the inverted divisor, as witness Brahmagupta's (*q.v.*) work of the seventh century; but it was only partially recognized in the Middle Ages in Europe. It reappears as a standard method in Stifel's (*q.v.*) *Arithmetica Integra* in 1544.

Complex fractions are not so modern as might be thought to be the case, for Rabbi ben Ezra gives examples of them in his *Sefer ha-Mispar*, written in the twelfth century.

**History of the Decimal Fraction.**—The decimal fraction has come into general use only within a century, although the theory was perfected by 1600. One of the most interesting of the early influences tending to the invention of the decimal fraction was a certain rule for the extraction of roots, expressed in modern symbols by  $\sqrt[n]{a} = \frac{\sqrt[n]{a} 10^{kn}}{10^k}$ . In particular,

$$\sqrt{3} = \frac{\sqrt{30000}}{100} \text{ or } \frac{\sqrt{3000000}}{1000},$$

the actual process of extracting the root being quite like our present one with decimals. This rule was known to the Hindus, and to Johannes Hispalensis in the twelfth century, and it appears again in the works of Johann von Gmunden (c. 1380-1442), Peurbach (1423-1461), and their successors until the close of the sixteenth century. The most interesting step from this rule in the direction of the decimal fraction appears in certain tables of square roots, in connection with which the statement is made that the numbers having been multiplied by 1,000,000, the roots are 1000 times too large.

Another influence leading to the invention of the decimal fraction was the rule for dividing numbers of the form  $a \cdot 10^n$ , attributed by Cardan (1539) to Regiomontanus. This appears in several manuscripts of the fifteenth century, as in the case of  $470 \div 10 = 47$ , and  $503 \div 10 = 50\frac{3}{10}$ . Borghi (1484) elaborates this rule, but it appears in its most interesting form in the rare arithmetic of Pellos (1492), who unwittingly made use of the decimal point for the first time in a printed work.

Later writers commonly used a bar for this purpose, as was the case with Rudolff (1526), Cardan (1539), Cataneo (1546), and various other writers. Even as late as the 1816 edition of Pike's *Arithmetick* (New York, 1816), 46,464 is divided by 7000 thus:—

$$\begin{array}{r} 7 \overline{) 000} 46 \overline{) 464} (6\frac{4164}{7000} \\ \underline{42} \phantom{00} \\ 4 \phantom{00} 464 \end{array}$$

The first man who gave evidence of having fully comprehended the significance of all this preliminary work seems to have been Christoff Rudolff, whose *Exempelbüchle* appeared at Augsburg in 1530. In this he solves an example in compound interest, and uses the bar exactly as we would use a decimal point to-day. If one man were to be named as the best entitled to be called the inventor of decimal fractions, Rudolff might properly be the man. His work, however, was not appreciated, and it was not until 1585 that a treatise upon the sub-

ject appeared. The first to show by a special treatise that he understood the significance of the decimal fraction was Stevin (1548-1620) who published a work upon the subject in Flemish, followed in the same year (1585) by a French translation. This work, entitled, *La Disme*, sets forth the method by which all business calculations involving fractions can be performed as readily as if they involved only integers.

The historical steps in the invention of the decimal fraction may be summed up as follows: Pellos (1492) used a decimal point where others had used a bar, but the idea of the decimal fraction was not developed by him. Rudolff (1530) operated with decimal fractions clearly, using a bar for the separatrix, but he did not write upon the theory. Stevin (1585) wrote upon the theory, but had a poor symbolism. About 1600 several writers attempted to improve the symbolism, and Bürgi, in 1592, actually used a comma for the decimal point, without the common sexagesimal marks, and comprehended the nature and advantages of these fractions. It is thus difficult to pick out the actual inventor, although Rudolff and Stevin are entitled to the most credit for bringing the new system to the attention of the world. It may also be said that the symbolism is by no means settled even yet. In England  $23\frac{45}{100}$  is written 23-45; in the United States it appears as 23.45; on the Continent it is given as 23,45, or often as  $23\frac{45}{100}$ . Indeed, in America, we commonly write \$23.<sup>45</sup> instead of \$23.45, to avoid forgery.

**History of Sexagesimal Fractions.**—The later Alexandrian astronomers used a system of fractions based on sixtieths, and these are known as sexagesimal fractions. Thus they wrote, in their notation,  $2^\circ 17'$ , for  $2\frac{17}{60}$ .  $2^\circ 17' 45''$  for  $2 + \frac{17}{60} + \frac{45}{3600}$ , and  $2^\circ 17' 45'' 30'''$  for  $2 + \frac{17}{60} + \frac{45}{3600} + \frac{30}{216000}$ . The medieval writers carried these fractions much further, as in the work of Sibte el-Máridimi (Bedr ed-Din Abou Abd-Allah Mohammed ben Mohammed ben Ahmed, of Cairo, c. 1450), where  $47^\circ 50' \div 1^\circ 25'$  is given as  $33^\circ 45' 52'' 56''' 28^{iv} 14^v 7^{vi} 3^{vii} 45^{viii} 52^x \dots$ , repeating after  $31^{xviii}$  (which is his last figure),—an interesting example of a circulating sexagesimal. That these fractions came originally from Babylon is generally assumed, the story seeming to have started with Achilles Tatius in the second or third century of our era. There is, however, no good authority for the statement, although the Babylonians used a mixed decimal and sexagesimal notation. In the Middle Ages these fractions were called physical or astronomical fractions. The Greek astronomers called  $\frac{1}{360}$  of a circumference a *μοίρα*, Latin *gradus*, whence probably our word *degree* (*de*, down, + *gradus*, a step). The Latin writers called  $\frac{1}{60}$  of a degree *pars minuta prima*, and  $\frac{1}{3600}$  of a degree *pars minuta secunda*, whence, by evident abbreviation, we have our minutes and seconds.

**The Teaching of Fractions.** — As will be seen from the preceding historical sketch, the subject of fractions has always been a stumbling block in the teaching and learning of arithmetic. The ancients avoided the difficulty by the use of compound numbers, but the demands of modern life necessitate more subtle divisions of the unit than are feasible by the ancient method. The crude system of compound numbers gradually gave way to the common fraction for many purposes; that in turn gave way to the sexagesimal fraction for finer divisions of the unit; and all three are now giving way to the decimal fraction. We have much less of compound numbers than was found a few years ago; our sexagesimal fractions are now limited to the expressing of time and of angle measure, and the latter will soon give place to the decimal divisions; and our common fractions are coming to be limited to the ordinary cases of practical measurement, the denominator rarely exceeding 64. With all this change has come the increasing importance of the decimal fraction, as witness the growth of such tables as those of the metric and monetary systems of the nineteenth century.

This being the case, several large movements are at present manifest in the teaching of fractions: (1) Common fractions are no longer taught as a topic at a single period in the pupil's progress, but they are scattered through the first five years of the elementary school, beginning with such unit fractions as  $\frac{1}{2}$ ,  $\frac{1}{4}$ , and  $\frac{1}{8}$ , always at first in a concrete fashion, working through the other unit fractions as the multiplication table (with its converse) is studied, and completing the formal treatment in the fifth school year. (2) Common fractions are generally limited to those needed in daily life, the denominator rarely exceeding two figures. (3) No attention is any longer given in elementary schools to the reduction of difficult fractions to lower terms. (4) The subject of complex fractions (forms in which one or both terms are fractional) is usually omitted. (5) The power to operate with decimal fractions is gained from a study of decimal tables (the metric system in countries where this is used, and the monetary tables in most countries, except where the British units are employed) before the subject is taken up in any scientific way. (6) The study of decimal fractions, while thus being mingled with the study of common fractions and the training in the operations with integers, is taken up in a scientific way after the study of common fractions has been completed. This is in accord with the historical development of the two kinds of fraction and with the psychological difficulties to be encountered. (7) The operations are taught with only as much of theory as is essential to an understanding of the processes, and without requiring the pupils to memorize explanations. (8) The intimate relations between different forms of fractions, as in the

identity  $\frac{1}{2} = 0.5 = 50\%$ , are emphasized, the pupil being encouraged to pass freely from one to another as conditions require. (9) The relation of the fraction to a ratio has occupied a good deal of attention of late, but it should be recognized that the concept of ratio is much more abstract than that of a fractional part of an object. (10) Three concepts of a fraction like  $\frac{3}{4}$  are recognized in elementary teaching: (a)  $\frac{3}{4}$  of a thing; (b)  $\frac{3}{4}$  of a group; (c)  $\frac{3}{4}$  as large, and the pupil is taught to use these several ideas in his problem work.

The details of explanation of the processes are sufficiently treated in the current textbooks, and the minor points of experiment are hardly of a nature to demand attention in this work. D. E. S.

**FRANÇAISE ALLIANCE.** — An association for encouraging the study of the French language in French colonies and foreign countries, with headquarters in Paris; founded in 1884 by Charles Tissot, Paul Bert, Paul Cambon, and Victor Duruy. It is essentially non-sectarian and nonpartisan, and seeks the coöperation of patriotic Frenchmen, diplomats, travelers, and missionaries. Its aims are: first, in French colonies and protectorates, to teach the French language in order to assimilate the natives; second, in countries still undeveloped to help teachers and Catholic or Protestant missionaries, by establishing and subsidizing schools in which French is taught; third, to establish relations with Frenchmen living in foreign countries, in order to preserve the cult of their national language. It recruits members and collects funds with which a large number of schools are subsidized in Turkey, Asia Minor, Syria, Egypt, and all over the world.

*Alliance Française de New York.* — A membership corporation organized in New York City in 1898, an outgrowth of the *Alliance Française* of Paris, and incorporated by special act of the Senate and Assembly of New York State on Mar. 22, 1907, with the particular object of encouraging in New York the study of the French language and of extending the knowledge of France, its literature, arts, history, and social life, and in general of developing social relations between the American and French people. The most important of the American groups of the *Alliance Française*, numbering 650 members in 1911, it provides for its members French lectures, entertainments, debates, dramatic performances. It established in 1902 the New York French Day Nursery, and entered into an agreement with Columbia University, offering every year two terms of free elementary courses for the study of the French language, for which 367 students registered during the academic year 1910-1911.

*Federation of the French Alliance in the United States and Canada.* — Incorporated in New York State in 1902; an outgrowth of

the *Alliance Française de New York* and of local groups organized in other cities between 1898 and 1902. It aims to coördinate the efforts of the various groups, and to encourage the organization of similar groups in other cities. It has a circulating French library of 2200 volumes, and in 1911 represented forty-six different groups of the *Alliance Française* and twenty-six other affiliated societies. It selects for these groups prominent French lecturers and extends its coöperation to American universities. Headquarters: New York, 117 Fourth Avenue. D. J.

**FRANCE, EDUCATION IN. — PRIMARY.** — Primary education in France at the present time is in a thriving condition. There are, without including the large number of private schools, not less than 68,728 common schools, which are maintained by the State, and are attended by about 4,400,000 boys and girls. The law compels each commune, whatever the number of inhabitants, to have at least one school for boys, and if the population is at least 500, to maintain a school for girls. But through the long centuries of the past popular education was entirely neglected. The different monarchic powers which succeeded each other, Royalty or Empire, were not at all favorable to popular education. It required the establishment of a democratic and republican government to break with ancient traditions of neglect and indifference, and for the conviction to arise that a country with universal suffrage must also have universal education.

**Historical.** — In the Middle Ages no other education was provided for the people than the catechism. "Reading and writing were also taught," remarks an author naively. But that was all, and this advantage only fell to the good fortune of a small number of children who were received into the schools which existed under the different names, episcopal, cloistral, or parochial, according as they were established by the bishops, cloisters, or the churches of the parish. (See MIDDLE AGES, EDUCATION IN.)

In the sixteenth century a resolution was passed at the States General at Orleans in 1560, in the instructions of the nobility, for the education of the young of the poor. But this resolution, inspired by the Protestant Reformation, received no attention, and was not renewed. In the centuries which followed the nobles no longer thought of addressing a petition in favor of popular education, and Diderot (*q.v.*) said, "There is no doubt but that it is more difficult to oppress a peasant who can read than any other man." In the seventeenth century a Catholic priest, J. Baptiste de la Salle (*q.v.*), established the Institute of the Brethren of the Christian Schools (see CHRISTIAN BROTHERS), a teaching congregation which has rendered real service

in a large number of schools down to the present day. But with its denominational character and mechanical methods the system could not adapt itself to the modern spirit, and like all the other congregations was suppressed by the law of July 7, 1904.

The Revolution of 1789 was marked by a large number of proposals, but there was neither the time nor the power of realizing them. Napoleon I established the University of France in 1806, but, occupied almost entirely with higher education, he paid no attention to primary schools. No provision was made for them in the Imperial Budget. The Restoration was no more generous, for it allowed only the ridiculous sum of 50,000 fr. for popular education as a mark of encouragement. This was the period of mutual instruction, introduced from England into France by imitators of Bell and Lancaster, but the transitory success of this method of instruction was at once proof of the lack of resourcefulness and the rarity of capable teachers. It spread everywhere for reasons of economy, since it allowed one teacher to instruct, with more or less success, even as many as four or five hundred pupils.

It was also under the monarchy that the law of June 28, 1833, known as the *Loi Guizot*, from the name of its author, at that time Minister of Education, organized elementary education for the first time. Henceforth there was to be a school in each commune, or at the very least one for a group of two or three communes. Another innovation of this law was the creation of a higher type of elementary education in the higher primary schools (*écoles primaires supérieures*), to be established in all the capitals of the departments and in communes of more than 6000 inhabitants. But on this point the law remained in part a dead letter, and the few higher primary schools which were established soon disappeared. The reactionary law of March 15, 1850, does not even mention their name. This is the *Loi Falloux*, which controlled public education throughout the Second Empire. It was enacted in a spirit of defiance to the wishes of lay teachers, and encouraged the development of denominational schools. The Church was at the time all-powerful, and no serious qualifications were demanded from teachers, provided they possessed ecclesiastical authorization, granted by the bishops and called *Lettre d'obédience*.

**Present Conditions.** — It is to the Third Republic that the honor belongs of having organized the system of elementary education. It succeeded in realizing what the leaders of the Revolution had only dreamed of. It established a system of national education very similar to that established by the democracy of the United States. It increased the number of schools, which were now established in the smallest villages. New and comfort-

able schoolhouses, which the malevolent call "scholastic palaces," were erected by the thousands. The right of the State to educate was vindicated, and teaching congregations were suppressed. While maintaining the freedom of instruction under certain conditions, elementary education was placed in the service of the State. Finally a system of universal education was established which was to be free, compulsory, and secular.

Ready consent was received for free education, established by the law of June 16, 1881. It was easily understood that the establishment of elementary schools, where a minimum of instruction should be given free to all the children of the nation, was a social obligation, and that free public schools ought to be open to all, rich and poor, and that arrangements made in preceding legislation, by which free education was only given to children of the destitute, should no longer be regarded as satisfactory. Besides, free education was the necessary corollary of compulsory attendance. But it was not without difficulty that the republican government succeeded in passing laws embodying the second principle. It required a strong minister like Jules Ferry (*q.v.*), who displayed remarkable energy, to secure a vote for compulsory education from Parliament (law of March 28, 1882). His efforts were seconded by an eminent educator, then Director of Elementary Education, M. Ferdinand Buisson. These two were the organizers, or, one might well say, the creators, of primary education in France. (See FEES.)

*Secularization.* — It was only gradually that the third characteristic of the French system, secularization, became a reality. In 1881 (law of June 16) the courses of study were secularized, and civic and moral instruction were substituted for religious education. In 1886 (law of Oct. 30) the teaching body was secularized by a provision that the public schools should no longer be intrusted, after a certain period, to clerical teachers and institutions. Finally a more recent law, July 7, 1904, continued the forward advance of the secular spirit by suppressing the teaching congregations, and closing as a consequence all the free schools directed by the congregations. The public schools are thus free, compulsory, and secular, but they are also neutral, in that the teachers must abstain when giving instruction from any word which would offend the consciences of the pupils and the belief of their parents. All incursions into the field of religion are forbidden. To each man his proper sphere; to the minister of religion the liberty of preaching the doctrine of the different churches, to teachers who teach in the name of the State, that is, of society, the right of limiting themselves to the field of universal human morals, together with the duty of refraining from any attack on religious beliefs. Neutrality is guaranteed by the secularization of

the teaching body, and it must be strictly observed. The opponents of the lay schools — they are still numerous — claim that it is frequently violated; and this year the French bishops have denounced a number of textbooks as not conforming to the requirement of neutrality. They demand that these books be excluded from the schools. Hence there are some difficulties which have not yet been settled by the recent laws.

*Duration of School Attendance.* — The legal period of compulsory attendance at the elementary school is from six to thirteen years of age, but as a matter of fact a large number leave before this age. The compulsory period is somewhat short, and efforts are being made to lengthen it. A recent law has extended the age at which pupils will in future be allowed to present themselves for the *certificat d'études primaires* from eleven to twelve. From different sides the demand is being made that the school period should be raised to thirteen or fourteen. A desire is also expressed from another quarter that it might be possible to organize a regular compulsory system of education, similar to the continuation schools of Germany, where the adolescents may continue their studies after fourteen years.

*Higher Primary Schools.* — Beyond the elementary schools there is an extension through the *cours complémentaires*, *écoles primaires supérieures*, *écoles professionnelles*, and *écoles manuelles d'apprentissage*. The *cours complémentaires* are classes added to the elementary schools. As their name indicates, they provide supplementary instruction to those pupils who are willing to remain at school after receiving the *certificat d'études*, a sufficiently diversified course, at once professional and general. In the majority of these courses some of the pupils prepare for the *brevet élémentaire* and the normal schools.

The higher primary schools are special institutions, located apart from the elementary schools and under a different director. They provide at least two, most generally three, years of study; the latter are said to be *de plein exercice*. To be admitted to these schools, as well as to the *cours complémentaires*, pupils must have the *certificat d'études primaires élémentaires*, and must have taken for one year the *cours supérieur* of a primary school. The curriculum of the higher primary schools continues and develops that of the primary school. In the most important of them special sections are established for agriculture, industry, commerce, and domestic occupations. The course of study, which was modified in 1909 to receive a more practical and professional character, includes, in addition to a fuller development of the elementary curriculum, the reading of literary works, common legal ideas, political economy, algebra, geometry, common rules of bookkeeping and accounts, and for boys the work of the shop, laboratories, agriculture, and

horticulture, for girls the care of children from their earliest age, and domestic arts. A committee of patronage is established over each school. The pupils who leave the higher primary schools enter on very diverse careers. Of the boys, according to official statistics, about 30 per cent enter industry, commerce, or agriculture, 15 per cent become employés in offices or stores, 8 per cent proceed to normal schools. Of the girls 17 per cent enter the normal schools, 6 per cent become workers or apprentices in clothes and dress factories, 4 per cent take employment in offices or stores.

*Courses for Adults.* — To complete the education of children who leave the primary schools at twelve or thirteen, and who cannot enter a professional or higher primary school, either through failure in examinations or because poverty in their homes compels them to enter on some employment as quickly as possible, evening classes, called *cours d'adultes ou d'apprentis* have been established. These courses are established in the same way as primary schools, that is, by the prefects at the request of the municipal council of the commune and on the advice of the Inspector of the Academy, and are placed under the control of the State, and may receive a state subvention on condition that the commune undertakes the cost of heating and lighting. They are usually under the direction of teachers, male or female, and every year a certain sum is inserted in the budget for their remuneration. These courses supplement the primary education, and in addition provide, according to the needs and means of the commune, more specialized instruction adapted to the industries or agriculture of the district. The pupils who pursue these courses, only open to those above fifteen years of age, and who have not obtained the *certificat d'études primaires*, may present themselves for an examination specially instituted for them, the *certificat d'étude des adultes*, which is evidence that they have successfully pursued the evening course. In 1910 there were 229 public higher primary schools for boys and 135 for girls, attended by 26,649 boys and 18,259 girls.

Besides the higher primary schools, where the instruction retains the character of general culture, there are some schools which prepare definitely for the vocations. Such are, first, the practical schools of agriculture, which may be entered at thirteen years of age after an examination. Tuition fees are charged. There are also manual apprenticeship schools and professional higher primary schools, which are regulated by decrees of Mar. 17 and July 28, 1888. They are under the direction of the Minister of Public Instruction and of the Minister of Commerce. The maintenance of these schools falls on the departments and communes, but the salaries of the staff are paid by the State. The pupils must be twelve years of age, and must have the *certificat d'études*

*primaires*. The course lasts three years, and instruction is free. To this list must be added the five following schools established in Paris, which are of great importance both in the quality of the instruction given and in the number of pupils. (1) *L'École Diderot*, where metal and woodwork are taught, (2) *L'École Boule*, arts and furniture, (3) *L'École Estienne*, arts and book industries, (4) *L'École Germain Piloy*, practical design, (5) *L'École Bernard-Palissy*, design and application of fine arts to industry. These schools are under the control of the Minister of Commerce. (See further INDUSTRIAL EDUCATION.)

*Écoles Maternelles.* — This is the name adopted in France to designate the Kindergarten, because the care there given to children recalls so far as possible the care given by a mother. These schools receive the children from the ages of two to six years, that is, up to the age when they are received into the primary schools. There should also be mentioned the existence of *classes enfantines*, which to some extent are intermediate between the *écoles maternelles* and the primary schools. They are attached either to an *école maternelle*, or to a primary school. "They are," according to the organizing decree of Jan. 18, 1887, "institutions for the earliest education, where children of both sexes receive in common the care which bears on their physical, moral, and intellectual development." Properly speaking, they are not schools, but the children are there prepared to pursue a school course. The program consists of games and songs, manual exercises, the first principles of moral education, the more common information, language exercises, the first elements of design, reading, writing, and number work. There are at present 2613 lay *écoles maternelles*, and 1498 private schools besides. The teaching staff is exclusively female. The directresses must have the *certificat d'aptitude pédagogique*. Supervision is exercised by the ordinary inspectors, sometimes, but rather rarely, by some departmental inspectresses, and by the general inspectresses of *écoles maternelles*.

*Mixed Schools.* — It is well known that co-education, which prevails to such an extent in the United States, has not entered into the French system. Still there are a few schools where boys and girls are together, under the direction of a male or female teacher. These are called mixed schools. There are more than 20,000 of these, with 718,873 pupils, or 718,880, if Algiers is included.

*Internal Organization of the Schools.* — Six hours of class work are given, from 8.30 to 11.30 and from 1.00 to 4.00, every day except Sunday, which is a day of rest, and Thursday, which is left free to permit the attendance of pupils at religious instruction outside the school. In addition, there are several holidays during the year, on religious festivals, New Year's Day, and on July 14, the national holiday. The

long vacations last for six weeks, from the 15th or the 20th of August to the end of September or the beginning of October. Two weeks extra are given in these schools in which the teachers have organized courses for adults and consequently have done full duty for the year. The long vacations also extend over two months, except in a certain number of schools which have established vacation courses and give one hour's instruction each day for a month. The periods are divided by recesses of a quarter of an hour, one in the morning and one in the afternoon. Pupils who cannot go home for their midday meal find in a large number of schools *cantines scolaires*, which provide lunch free or at a very modest price of ten, fifteen, or twenty centimes (two, three, or four cents). In the afternoons pupils may be authorized to remain at school to do their home work and to learn their lessons under the supervision of a teacher; this is called supervised instruction (*études surveillées*), which is given in some cases gratis, in some not.

The curriculum is divided into three grades, *cours élémentaire*, for pupils between six and nine years, *cours moyen*, for pupils between nine and eleven, and the *cours supérieur*, for pupils between eleven and thirteen. In the schools with a large enrollment each *cours* constitutes a distinct class under a separate teacher, and sometimes, when the numbers are very big, there are two parallel classes of equal standing, each under a teacher. There are also schools with a very large number of classes, up to ten, twelve, or fourteen. Each class must have at least fifty pupils.

Schools which have many classes, and consequently many teachers, have a director at their head. The directors are selected from among those teachers who have served a certain number of years and have distinguished themselves by their excellence. They receive an additional salary, which varies from 200 frs. in schools with three classes, to 100 frs. in schools with four classes. In those schools which have six classes and 300 pupils, the directors no longer give instruction; they are freed from class duty and devote themselves entirely to the material and moral direction of their schools.

*Curriculum.*—This includes those elements of knowledge which are taught in nearly all the states of America and Europe, omitting, of course, religion. This instruction is more markedly theoretical than practical. "Its object," said Gréard, the true organizer of the school system of Paris, "is not to include under all the branches with which it deals all that can possibly be known, but to learn in each of them that which cannot be ignored." Active, intuitive methods are employed for developing the senses and intelligence of the children. At a recent conference some teachers showed an inclination to give a more practical, more vocational, stamp to primary instruction.

But their proposal was not accepted, and the large majority of their colleagues remain attached to an educative instruction in general culture to mold the man and the citizen.

*Operation of the Compulsory Attendance Law.*—To insure the execution of the compulsory attendance law, two methods, *commission scolaire* and the *caisse d'école*, were established by the parliament of 1882. Children who do not attend regularly must be reported by their teachers to the *commission scolaire*; the parents, who are held civilly responsible, are condemned to penalties which in case of a repetition of the offense are public posting of their names, fines, or even imprisonment. Unfortunately these boards have not yet done their duty, and their inactivity explains the fact that there is still in France too large a number of illiterates. More than 10,000 conscripts enter the army each year without being able to read or write. There is a proposal to alter the composition of the boards, which at present is too exclusively municipal and local. Reference may here be made to the recent establishment of *écoles de perfectionnement* for backward or abnormal children (law of April 15, 1909).

The *caisses d'école* are intended to assist the children of poor families by providing them free with books and paper which they cannot buy, and also by occasionally distributing clothing. Under certain circumstances these boards may be subsidized by the State.

*Certificates and licenses.*—The diplomas expected from the teacher are the qualifying certificates, *brevet élémentaire* and *brevet supérieur*, the examinations for which are regulated by the decree of Jan. 10, 1887, and Aug. 4, 1905. Further there are (1) the *certificat d'aptitude pédagogique*, the necessary requirement for permanent appointment, and various certificates of professional ability; (2) *certificat d'aptitude au professorat* in normal and higher primary schools; (3) certificates for inspection of primary schools, the direction of normal schools, and inspection of *écoles maternelles*. There are, besides, other certificates for special subjects,—modern languages, bookkeeping, manual instruction, and dancing.

For the pupils there are two certificates: (1) the *certificat d'études élémentaires*, which is, as it were, the graduation in elementary studies; the examination for the certificate may be taken at the age of eleven, but a recent law has postponed the age to twelve. About 10 per cent of the pupils ask for and obtain the certificate at this age. (2) *Certificat d'étude primaire supérieure*, which is awarded on a written, oral, and practical examination covering the whole course.

*Inspection of Schools.*—The inspection of schools is conducted primarily by the heads of the institutions who supervise the work of the teachers and pupils, and secondly by special officials who bear the name of inspec-

tors. Of these there are, first, the inspectors of primary education, at least one to each district (*arrondissement*), three or four to each department, and 454 in all. They are nominated by the Minister, and must possess a special diploma, the *certificat d'aptitude à l'inspection des écoles primaires et la direction des écoles normales*, obtained by competitive examination, for which teachers, male and female, at least twenty-five years of age, with five years of service and holding the *certificat d'aptitude au professorat des écoles normales*, or a license to teach in secondary schools, are eligible. Teachers who hold only the *brevet supérieur* and the *certificat d'aptitude pédagogique*, if they have served ten years, are also admitted. The primary inspectors must visit the schools of their circumscription each year. After each visit they must inform their superordinates in a written bulletin in what points their work was satisfactory or in what it was inefficient. In addition to the duties of inspection, the inspectors are charged with administrative functions; they advise on the appointment and promotion of teachers, on the erection and construction of schools, etc.

Over the primary inspectors are the inspectors of academies, who are really the heads of departments for primary education. These officials, who also play an important part in secondary education, appoint the *stagiaires*, propose the names of *titulaires*, male and female, to the prefect, receive the reports made to them by the primary inspectors after each inspection, and preside at the administrative councils of normal schools, etc. Finally, the general inspectors of primary education, to the number of ten, supervise the whole system of instruction. They are sent annually on a mission to the schools of Paris and of the departments. There are also general inspectors of accounts, of design, and of gymnastics.

The powers of the rectors are various. Their authority extends over the three fields of education, but so far as primary education is concerned is very limited, since they do not take part in the appointment of the teachers, which devolves on the prefects and the inspectors of the academies, and is only exercised by the rector of Algiers. It would be logical that this practice should be followed in all the academies, and that the appointment of teachers should be made by the university heads, and not by a political official, like the Prefect of the department. This reform has been projected several times, but up to the present without success.

*Departmental Council.* — There is, further, in each department, a departmental council, presided over by the prefect and consisting of general councillors, of teachers, and inspectors. This council appoints the cantonal delegates representing families, as well as the teachers, specially charged with the examination of the condition of premises, equipment,

health, and conduct of the pupils. They determine the number, nature, and location of public primary schools, the number of teachers employed therein, and supervise the carrying out of the curriculum. This is one of the most important organizations in the administration of French elementary education. It is still charged with the duty of advising on certain disciplinary penalties imposed on teachers (temporary or permanent suspension), and of deciding others (censure, revocation). The teachers may appeal against these penalties before the *Conseil supérieur de l'instruction publique*.

*Normal Schools.* — The professional preparation of teachers is secured in the normal schools. There should, according to the general principle, be one normal school for boys and one for girls in each department. But recently, through reasons of economy, two contiguous departments have been authorized to make agreements to unite for the establishment of a normal school. Hence there are only eighty-five normal schools for male teachers and eighty-four for women teachers. The students are admitted by a competitive examination, and remain for three years. With two exceptions (Ajaccio and Maçon) these schools, which are free, are boarding schools (*internat*). The students must hold the *brevet élémentaire* before presenting themselves for the examination. At the end of the second year they take the examination for the *brevet supérieur*; and during the third year, which is more strictly professional, they receive their direct practical training in school instruction in the practice schools (*écoles annexes*) attached to the institutions. Here they give the instruction by turns under the direction of their teacher.

Each normal school has at its head a director, man or woman, assisted by a bursar and an administrative council. The professors of letters and of science number 378 in the normal schools for men, and 364 in those for women. They are appointed by the Minister after a competitive examination, to which only teachers twenty-one years of age, and holding the *brevet supérieur*, and with two years of service, are admitted, and as a result of which the *certificat d'aptitude au professorat des écoles normales* is given. To facilitate the preparation for this examination there are two primary higher normal schools, at St. Cloud for men, and at Fontenay aux Roses for women. They are, like the normal schools, free, and entrance is regulated by competitive examination. The students must be from nineteen to twenty-five years of age, must have the *brevet supérieur*, and bind themselves to serve for ten years in a public school, an obligation into which candidates for the normal schools must also enter.

*Appointment of Teachers.* — On leaving the normal schools the graduates are appointed by the inspector of the academy as temporary

## FRANCE, EDUCATION IN

teachers (*stagiaires*), and serve for a period of at least two years in one school, at the end of which they are allowed to present themselves for an examination on passing which they are awarded the *certificat d'aptitude pédagogique*, and which includes a written, oral, and practical test. The last consists of class lessons given to pupils in the presence of the examining commissioner. When they have obtained this certificate, which is evidence of their professional ability, the *stagiaires* are appointed permanently under the name of *titulaires* by the prefect on the recommendation of the inspector of the academy.

The normal school pupils and the pupil teachers number more than 10,000. In 1907, after the three years of study, 1616 men left the normal schools, and 1675 women. This annual training of more than 3000 students does not always suffice to fill the vacancies. A call is therefore made on those candidates who hold the *brevet supérieur*.

*Disciplinary Penalties.*—A graduated system of penalties for teachers in primary schools was established by the law of Oct. 30, 1886. The penalties and the authorities who impose them are, (1) reprimand by the inspector of the academy, (2) censure by the inspector of the academy on the advice of the departmental council, (3) dismissal by the prefect on the recommendation of the inspector acting on the advice of the same council, (4) temporary suspension, and (5) permanent debarment by the council, from which the offender may appeal to the Superior Council of Public Instruction.

*Administrative Authorities.*—The supreme head of the system is the Minister of Public Instruction, who is assisted immediately by three directors, one for each of the three branches of education, primary, secondary, and higher. There is further a fourth director of accounts, charged with the administration of the expenditure of the department. Each director is at the head of several bureaus, each with special functions.

Below the Minister come the rectors, who are charged with the administration, in his name and under his order, of the seventeen educational divisions of France, called academies. In the Academy of Paris there is only a vice-rector, the title, if not the duties, of rector belonging to the Minister himself. The sixteen other academies are Aix, Besançon, Bordeaux, Caen, Chambéry, Clermont-Ferrand, Dijon, Grenoble, Lille, Lyons, Montpellier, Nancy, Poitiers, Rennes, Toulouse, and Algiers.

*Cost of Primary Education.*—The budget for primary education is large. (See COST OF EDUCATION. As explained under this topic an accurate comparative statement of the cost of education in various countries is not possible.) The details of the sums included in the budget for 1910 are as follows:—

## FRANCE, EDUCATION IN

Salaries (not including towns with more than 150,000 inhabitants)	177,193,800 francs.
Contributed by the State to towns of over 150,000 population	5,000,000 francs.
Higher primary education	4,878,246 francs.
Normal schools, salaries	4,300,235 francs.
Normal schools, equipment	4,866,000 francs.
Higher primary normal schools	325,600 francs.
Inspection	2,466,350 francs.
General inspection	130,000 francs.
Bursaries (for traveling and foreign visits)	800,000 francs.
Expenses of substitutes and sick pay	1,043,200 francs.

This gives a total of expenditure amounting close to 200,000,000 frs. To this must be added the expenses of the communes, first those with a population over 150,000, which contribute a large share toward the salaries of teachers, and then all the communes, which must pay compensation for rent and lodgings. Further an annual credit is inscribed in the budget for the creation of schools and posts. The State has spent enormous sums on this for the last thirty years, and in 1910 set aside, 680,000 francs.

*Salaries.*—The claim has frequently been made that women teachers be paid equal salaries with men, on the principle of "equal work, equal qualifications, equal pay." But this principle does not yet prevail in the legislation of France, and the women are paid less than the men, at any rate in the third, second, and first classes.

CLASS	MEN	WOMEN
	frs.	frs.
<i>Stagiaires</i>	1100	1100
<i>Titulaires</i>		
Fifth	1200	1200
Fourth	1500	1400
Third	1800	1600
Second	2000	1800
First	2200	2000

To the fixed salaries are added compensation for rent in the communes which are the capitals of cantons, or where the population is above 1000. This compensation varies with the population; in districts of 1000 inhabitants it is 100 frs., and rises to 800 frs. in very large towns, and to 2000 frs. in Paris.

*Pensions.*—Teachers have a right to a retiring pension at the age of fifty-five, and after twenty-five years of service. But a large number, if they are still in good health, continue in their duties beyond this. The law of Aug. 17, 1876, which regulated the matter, fixed the amount of the pension at not less than 600 frs. for men and 500 frs. for women.

*Auxiliary Institutions.*—To present an almost complete idea of the system of primary education it would be necessary to mention various institutions auxiliary to the school. (1) *Conférence pédagogique*, a periodical assembly to which the *titulaires* are summoned to

discuss educational questions, and to draw up a list of school textbooks. (2) *Libraries* of three types: (a) pedagogical for use of teachers, one in each cantonal capital, (b) for pupils, one in each school, and (c) public, for the parents as well as the children. (3) *School savings banks*, which aim at instilling in the pupils early habits of order and thrift. (4) *Musée pédagogique*, located in Paris and containing school equipment, teaching apparatus, and a good library, which is open to readers in Paris, and also circulates its books and lantern slides in the provinces, sending them free on request. There is further at the Museum a Bureau of Public Education. (See MUSEUMS.)

*Private Education.*—Before the law of 1904, which suppressed the teaching orders, the number of private schools under the congregations had risen to 6157: 1288 schools for boys under the Christian Brothers, and 4869 schools for girls under Sisters of different orders. These schools were gradually closed by the operation of the law of July 17, 1902. Several schools still continue; there were, on June 1, 1909, fifty-six schools of the Christian Brothers and 833 schools of Sisters. Further, a large number of the closed schools have been reopened with a lay or secular staff; the members of the orders having exchanged their ecclesiastical garb for civilian mufti. On June 1, 1909, there were 3069 reopened as private lay primary schools, 992 for boys and 2077 for girls. The private schools are established and maintained by individuals or by associations. The State leaves them free in respect to curriculum and method, but the same qualifications as to age and ability are demanded from their teachers as from public school teachers. The formalities for opening a private school consist of a declaration made to the mayor of the commune indicating where the school is to be established.

**SECONDARY EDUCATION.**—**Historical.**—Secondary education was officially established by the law of May 11, 1806 (confirmed by decree of Mar. 17, 1808), by which the University of France was founded, as an instructing corporation, standing alone and dependent on the State. Until that time education had remained almost entirely a matter for the Church. The universities themselves, which in their faculties of arts gave an education equivalent to the secondary, were dependent on the ecclesiastical authority. But above all the religious corporations, and in particular the Society of Jesus, established in 1540, monopolized education. In the seventeenth and eighteenth centuries the colleges of the Jesuits flourished above all others, and retained that position until they were closed in 1764, when the Jesuits were expelled from the kingdom. Another religious corporation, the Oratorians, took their place to some extent, and for a time were successful. But the Revolution broke out and suppressed the universities and the

congregations. To replace the colleges there were established central schools, composite institutions, which combined industrial arts and literary studies and met with but moderate success. They disappeared after a few years, being abolished by the law of May 1, 1802. It was then that Napoleon created out of all the sections the University of France, which, with some special faculties of higher education, united the lycées and colleges of secondary instruction. The University of France still exists, at least in name; and it is to be regretted that there is but one word to denote, on the one side all the scholastic institutions, and on the other the institutions for higher learning, recently reconstituted under the title of university—but how changed and different from what it was originally! Napoleon had invested it with a monopoly in education, and it alone was charged with the provision of national education, while now this monopoly no longer exists, and the freedom of instruction has been legally established; and although the monopoly of the university is demanded in some quarters, there is reason to believe that freedom will be maintained because it conforms to republican principles. Further, the curricula of secondary education have been considerable modified. Under the pressure of the modern spirit there has been a failure to retain certain studies, while others, notably modern languages, have been introduced; there has been a discontent with the classical studies and the old humanities, and an adaptation of the curriculum to modern needs of society. Hence a lycée of 1910 bears little resemblance to a lycée of 1810, where almost nothing but Latin and mathematics were taught.

After the fall of the First Empire, the imperial lycées became the royal colleges. Again becoming lycées under the Republic of 1848 and the Second Empire, there was no palpable change in their character. It may be recalled only that for a time the studies were divided into two sections—letters and science; this is known as the period of bifurcation. And this arrangement was further divided under the Third Republic, and modern instruction, without Latin or Greek, was distinguished from the classical, a system already in operation under the Second Empire, when special instruction was established.

**Present Conditions.**—The system of secondary education was regulated anew by the decree of May 31, 1902, which was inspired by the report based on a parliamentary inquiry, organized in 1899 and presided over by M. Alexander Ribot, the Prime Minister. In the course of the inquiry the most competent educators in the country were consulted. The system has now been in force eight years, and, while objections and criticisms have been raised, it is generally accepted, and it seems that it will stand, although past experience shows that in such matters there is nothing final. Second-

ary education has been frequently altered during the last century without ever receiving a lasting character; so that it would not be cause for surprise, if within a few years new changes were proposed and accepted. There is no need to disguise the fact, for of the three branches of education the secondary has been the most discussed in France. Elementary education may be left out of consideration, for it depends on the needs of a democracy. Higher education does not meet with opposition. But intermediate education, which is the education of a class, since it is provided almost entirely for children of the middle class, is sometimes questioned. Its utility is not always recognized. It is not borne in mind that it is indispensable for the intellectual training of the nation, that before the period of specialization the youth of the country must pass through a stage of general culture, that even in a democracy, jealous of the rights of equality, it is not possible to give a thorough education to all, that a broader and more complete education must be reserved for a few; and, finally, that to train an intellectual élite there are required time, long study, and better prepared and better educated professors than are the teachers of the elementary school. These reasons will undoubtedly triumph over the prejudices of the masses, who in their ambitions are sometimes inclined too much to be levelers. Secondary education will be maintained, not gratuitously, it is true, like elementary, for it is just that those who are rich should pay, and will be made more and more accessible to the able but less fortunate children by means of scholarships which the State grants with a liberality which is always great.

*Course of Study of 1902.*—The following are the main characteristics of the course of study of 1902. The most striking feature is that, in place of the one single and uniform course for all pupils, several are provided for their selection. Here is obvious the influence of the elective courses common in the United States, whose existence and success were noticed by the present writer in the *Report on American Secondary Education*, presented after his return from the World Exposition at Chicago to the Minister of Public Instruction in France in 1893. The courses last seven years. Pupils are received at the age of ten or eleven, and remain to seventeen or eighteen, the age of graduation. The school period is divided into two cycles, one of four and the other of three years. In the first cycle, sixth, fifth, fourth, and third forms, the pupils have a choice of two sections. In the one, called Section A, are taught Latin, compulsory from the first year (sixth form), Greek, optional from the third year (fourth form), as well as subjects common to both sections: French, modern languages (English or German), arithmetic and mathematics, natural sciences, history, geography, and drawing. The second

section, called Section B, differs from the first in not including Latin or Greek, and in paying more attention to French (five hours instead of three), and to the sciences. In both sections in the fourth and third forms elementary moral instruction is given for one hour a week in the form of lectures and discussions on individual and social duties.

The system of electives, or *quadrifurcation*, is offered in the second cycle in the second and third forms. The four groups are (1) Section A, in which, besides the studies common to all, Greek and Latin are studied (Græco-Latin section); (2) Section B (Latin-modern-language section) has three hours of Latin as before, and seven of modern languages (English or German), of which three are given to the language already studied in the first cycle, and the four to the other; (3) Section C (Latin-scientific section), in which the sciences predominate, five hours being given to mathematics, three to physics and chemistry, and three to Latin; (4) Section D (Scientific-modern-language section), in which Latin disappears altogether, the section being exclusively modern and French, with five hours for mathematics, three for physics and chemistry, two for practical scientific work, and seven hours for modern languages. This section is gradually replacing what was known as special and modern instruction.

Such is the course of studies, flexible and varied, in the second and first (formerly the rhetorical) forms. There remains one year, the seventh, in which the pupils divide into two forms, the philosophical and mathematical. In the philosophical are taught mainly philosophy, history, mathematics, physical and natural sciences, while Greek, Latin, and modern languages are optional. The mathematical form retains the study of modern languages and a little history, while the greater part of the time (seventeen hours) is devoted to the sciences.

This is the normal organization of the courses; but it must be mentioned that in the important lycées there are also special classes preparing for the great schools like the military school at St. Cyr, the Polytechnic, and the *École Centrale*. Further, in a certain number of lycées there has been established a fifth section with a shorter course of study (three or four years), based on modern languages and sciences, which are taught throughout with a view to their practical application. This system has certain points of resemblance with the German *Realschule*, where pupils are prepared for a practical career, industrial or commercial. Finally, in all the lycées and colleges there are elementary and primary classes (seventh, eighth, ninth, tenth, and *classe enfantine*). Elementary studies are the necessary basis of all secondary instruction, and can be acquired in the schools as well as in the lycées or colleges. A large number of pupils, therefore, do not

enter the lycée or college until the sixth class, the first year of secondary studies, that is, on leaving the primary schools.

*The Baccalaureate.* — The degree of bachelor forms the natural culmination of secondary education; it is the reward which crowns the studies. The baccalaureate has been frequently attacked; press campaigns have been conducted for its suppression, but it resists all attack. It is the necessary passport for entering on higher study. How else than by final examination is it possible to know whether a student has profited in his secondary studies and is fit to pursue a course at the university? Attempts have, indeed, been made to ameliorate the conditions under which the examination is taken and to correct certain defects about which there have been complaints. These dealt first with the enormous task imposed by the examination on the professors of the faculties of letters and sciences, who until recently were alone charged with the duty of examining, and who were diverted from their proper function of giving higher instruction and engaging in private research. France is a remarkable country, said a German educator; they use razors of the finest edge to cut stones! The professors of the faculties, who are here referred to, certainly take part always in the baccalaureate examinations; but though they preside at them, they are partly freed from this ungrateful task by the assistance of a board of professors of the lycées who are the most competent to appreciate the results of secondary education. They are placed on the boards of examiners, provided that they are *agrégés*, or doctors, and also, to insure impartiality, on condition that they do not question the pupils of those schools where they themselves are teaching. Another objection raised against the examination is the luck, the chances in an examination which lasts but three quarters of an hour, and in which outside examiners, the professors of the faculties, are called in to decide on pupils whom they do not know. To remedy this defect there have been introduced report books (*livres scolaires*) in which the professors of the different classes note down in advance, year by year, the marks gained by their pupils, and the boards of examiners must make themselves acquainted with these books before deciding on the admission or postponement of candidates.

The division of studies into several sections has as a consequence the division of the examinations for the baccalaureate. There are two distinct parts, which the candidates pass successively at an interval of a year; the first part comes on leaving the first form, the second at the end of the philosophy or mathematical forms. In the first part there are four series of examinations, corresponding to the four sections. The candidates of sections A, B, and C have a written test, including a French composition and a Latin translation; those of A have in addition

a Greek translation, those of B a composition in a foreign language, and those of C exercises in mathematics and physics. Candidates from section D also have three exercises, French, a foreign language, and science. The written tests are merely qualifying examinations. Those candidates who are successful are declared to be admissible, but are not admitted until they have passed the oral tests, which consist of suitable questions on the subjects studied in the different sections.

The second part of the baccalaureate, which must be successfully passed to become a complete bachelor, is based on the studies of the classes of philosophy or mathematics. There are thus two distinct examinations: (1) the baccalaureate of philosophy, the examination for which consists, for the written test, of a dissertation on a philosophical subject and a composition on the physical and natural sciences; (2) the baccalaureate of mathematics, with a mathematical test, exercises in science, and a composition in philosophy.

The boards of examination meet twice a year and hold their sessions one at the end and one at the beginning of the scholastic year, that is to say, in July or August, and October or November. Candidates for the first part of the examination must be sixteen years of age, but exceptions are made by the Minister when candidates seem to be likely to succeed, even though they have not reached the required age. The number of bachelors created each year is considerable. The following are the results of the session of July, 1910:—

	NUMBER OF CANDIDATES	REJECTED AFTER WRITTEN TEST	PASSED FINALLY	PASSED PER CENT
<i>First part:</i>				
Latin-Greek . . . . .	2334	934	1092	47
Latin-modern-languages . . . . .	3251	1536	1344	41
Latin-science . . . . .	2777	1222	1318	48
Science-modern-languages . . . . .	4299	2278	1648	38
<i>Second part:</i>				
Philosophy . . . . .	5745	2004	3045	53
Mathematics . . . . .	3355	1057	1923	58

Candidates who are put back at the July session present themselves again in October; those who have passed one part may retain credit for one year, and need not take the written test again. In October, 1909, there were 5052 candidates, of whom 2546 were admitted to the first part, and 3367 candidates, of whom 2214 were admitted to the second part. This makes a total for 1909 in both sessions of 6036 bachelors. It may be noted that the number of candidates who are put back is very large, often more than half; that the results are better for the second part than for the first; that the number of candidates is much larger in section D than in any other. It is obvious

that the baccalaureate is much sought after in France, for it opens the door not only to the universities, but to all careers. In spite of the diversity of the examinations which are conducted, there is only one baccalaureate of secondary education, and graduation in philosophy or mathematics confers the same privileges. The baccalaureate in law is gained after one year of study in the faculty of law.

*Other Degrees.* — Above the degree of baccalaureate come the *licence*, which is sought by future professors, then the doctorate and the *agrégation* (*q.v.*), which is a professional examination. There are several licentiate: (1) four licentiate of letters corresponding to the four kinds of study — philosophy, history, classical languages and literature, and modern languages. (2) Licentiate in science, which is conferred without any further examination on all students who possess these certificates of higher studies in mathematics and physical and natural sciences. (3) Licentiate in law, obtained in the faculty of law after three years of study. The different licentiate are conferred by the faculties of letters, sciences, and law. The statute on licentiate in science was regulated by decree of Jan. 22, 1896, (that for letters by decree of July 5, 1907). The doctorate in letters and the doctorate in science can only be conferred on those holding the licentiate. To obtain the doctorate two theses, which are often works of importance, must be presented and defended publicly before a faculty. The third degree is only sought by candidates who look to higher education; from 1810 to 1910, a century, not more than 1333 doctorates were granted by the faculty of letters, and less in the faculty of science. *Agrégation* is not a degree, but a title required for appointment as professor in a lycée. A competitive examination takes place each year before special boards of examiners, and only candidates holding the licentiate are allowed to present themselves. There are several kinds of *agrégation* — philosophy, history, letters, grammar, English, German, Spanish, Italian, mathematics, and physical and natural sciences. (See *AGRÉGATION*.)

*Lycées for Boys.* — Lycées for boys at present number 108. They are nearly all located in capitals of departments, a few in capitals of specially important *arrondissements*. The number of pupils in attendance in 1909 was about 60,548; in 1875 there were 38,000, and 54,830 in 1901. There is thus a considerable increase. The dispersion of the congregations, the suppression of the colleges of the Jesuits, Dominicans, and Oratorians brought back to the state schools a part of their clientèle. But only a part, for a number of free colleges were reopened under the protection of the bishops or civil societies, and gathered in the heritage of the congregations. The number of pupils who attend these schools may be estimated to be about 50,000.

It is to be noted that while the total number of pupils in the lycées has increased, the number of intern pupils has diminished. In 1885 there were 25,000, while in 1908 there were not more than 17,000. The *internat* is clearly on the decrease, at any rate in the establishments of the State. But there is no need to complain or to regret the time when there were seen crowded together in certain lycées of Paris as many as seven or eight hundred intern pupils. It is to the advantage of families, when they can do it, to retain their children in their midst.

*Colleges.* — The number of pupils who attend the colleges has not varied within the last thirty years: 35,438 in 1875, 36,282 in 1908. Here, too, the intern system has declined: 14,671 intern pupils in 1875, 12,854 in 1908. The colleges differ from the lycées in the first place because they are maintained by the State and by the municipalities; secondly, the colleges are communal, the lycées are national; their importance is less, and their professors do not hold the same degrees.

*Administration of Lycées and Colleges.* — Each lycée is directed by a *proviseur*, or headmaster, who is expected to act as the senior of the institution by the constant supervision exercised by him, by his advice to the professors, by the remarks which he makes to the pupils. He is assisted by a *censeur*, who is more especially charged with the supervision of discipline and the good progress of the studies. Other assistants are the *économique*, or bursar, on whom falls the financial management; one or more *surveillants généraux* or general supervisors; several *répétiteurs* (tutors), who supervise the study periods and of whom a few take part in instruction, with the title of adjunct professors. All these officers are nominated by the Minister. For the material surveillance of the boarding establishment and the dormitory, with which the tutors were formerly charged, there have recently been created *surveillants d'internat*, who are selected by the headmaster from a number of young men, generally graduates, who wish to continue their studies. Finally, the *proviseur* is assisted by an administrative council, consisting of men of prominence, members of the alumni associations, local authorities, the rector, the prefect, the mayor, and a professor of the lycée.

*Teachers in Lycées and Colleges.* — To obtain a permanent appointment in a lycée, candidates must have the title of *agrégé*, in a college the degree of licentiate or bachelor; but the instructing staff in a lycée must include some *agrégés*, and in a college some licentiate. In the lycée there are 1820 *professeurs agrégés*, and 723 licentiate who do not bear the title of professor, but are merely acting teachers. But some recent regulations have permitted a certain number of acting teachers to enjoy the title and pay of professors. In the colleges the staff is divided into three classes, professors

of the first rank, holding the licentiate and numbering 1625 in 1908; professors of the second rank, who are only bachelors, to the number of 613; professors of the third rank, to the number of 299, who do not hold the bachelor's degree, and only have the *brevet de l'enseignement primaire*.

*Training of Teachers.*—The training ground of professors of the lycées has been throughout the nineteenth century the Higher Normal School in the Rue d'Ulm. Since the establishment of the universities, this school has ceased to enjoy an independent existence; it has continued to the present, but only as part of the University of Paris, whose students attend courses at the school. In addition, a certain number of scholarships are awarded after competition to candidates for the degrees of licentiate and *agrégé* and divided between the universities of Paris and the provinces.

*Inspection of the Lycées and Colleges.*—This duty is exercised by the rector, the inspector of the academy, and general inspectors, of whom there are sixteen, four for science, four for letters, two for history, three for modern languages, one for philosophy, and two for the inspection of accounts (*économat*). They visit the different institutions each year, and send a report to the Minister on each officer inspected, on the condition of each institution. They meet in Paris, where sits the consultative committee (section for secondary education) of which they are members, and this body recommends to the Minister the appointments, dismissals, and promotions which appear desirable in the teaching body. Once each year the rectors are invited to take part in the work of the consultative committee, especially to arrange the list of teachers who are to be promoted, that is, who are to receive an increase of salary. The teachers are divided into several classes with different salaries, and promotions take place in a strictly definite order, some by seniority, some by selection.

*The Curriculum.*—The courses of study have been fixed for each form by the decree of May 31, 1902. It may justly be said that every branch of human knowledge is there represented, to insure general intellectual culture. The decree mentioned above also determines the weekly division of subject matter. The length of each period is usually one hour. In the higher forms of philosophy and mathematics, with the older boys whose attention is more sustained, the length of a lesson may be two hours, broken by a short recess.

As distinguished from primary education, secondary education includes religious instruction for those who desire it in the lycées. The services of the Roman Catholic Church are celebrated in the chapels of the lycées. Religious instruction is given by the chaplains, abbés, pastors, or rabbis. But the whole

question of religious instruction is under discussion and in a state of transition. Within the last year, an addition has been made in certain lycées to the intellectual education by the introduction of manual training and the establishment of workshops in iron and wood.

*Method.*—Methods are perhaps of greater importance than the curriculum. Considerable pains have been taken to improve them. Precise and detailed instructions have been included in the course of study of 1902, which point out the method to be followed in each subject. Only the most important points will be indicated here. French, which of course is studied in every form, except the philosophical and mathematical, is to consist of explanatory reading of authors by means of and with reference to the texts which are used in teaching history of French literature. In all the classes French compositions are set, in the form of descriptions, narratives, letters, and, later, dissertations. The chief aim of modern language instruction is to secure the thorough acquisition of the language studied, the ability to write and speak English or German. In the lycées which are near Spain or Italy, Spanish or Italian is taught as the second modern language. The direct method, which insists on use, rather than grammatical study, is employed by the teachers. In the teaching of Latin emphasis is laid on translations, while composition is not neglected. Latin verse and speech have, however, been dispensed with. In the study of physical science the experimental method is used so far as possible. Generally the active methods are employed; that is, those which tend to awaken the intelligence, and appeal to the judgment rather than to memory.

*Educative Forces.*—The lycées and colleges do not seek only to enlarge knowledge; their aim is educative as well as instructive. "The final end of instruction is education," according to the official directions. The development of physical education and life in the open is recommended; all exercises and games which can ensure physical suppleness and vigor must be placed within the reach of all. Gymnastic exercises are regularly indulged in, and the Swedish system, which was followed for some time, is being supplanted by the system of M. G. Demy. Athletics, and especially football, are increasing, and accidents are rare. Further, hygiene has a place on the program in the classes of philosophy and mathematics. As far as intellectual and moral education are concerned, the teachers are expressly advised to direct all their instruction to this end. While transmitting positive knowledge to their pupils, they must think more of forming their character than of giving a stock of information, after the maxim of Montaigne that "A head well-formed is much better than a head well-stocked." They must also develop character by encouraging initiative and energy.

*Salaries of Teachers.*—The question of

salaries is too complex to permit a detailed account. Here it need only be remarked that within the last few years attention has been paid to some measure of betterment and improvement. The salaries of *professeurs* vary according as they are *agrégés* or not; according to which of the five classes, into which they are distributed, they belong; and according to their residence in Paris or the provinces. The best paid *professeur* in Paris reaches 11,000 frs. (\$2200); in the provinces the lowest salary is from 8000 to 9000 frs. (\$1600 to \$1800). The salaries of teachers are just as variable. A *professeur agrégé* begins in the sixth class with 3300 frs. (\$650), advancing up to the first class with 5300 frs. (\$1060), and the special class with 5800 frs. (\$1160); but teachers in this class are very few, and only number forty-eight. The condition of teachers in Paris lycées is better; beginning with 5100 frs. (\$1020) they rise to 7600 frs. (\$1520) in the first class and 8600 frs. (\$1720) in the special class. The salaries of acting teachers vary from 2900 frs. (\$580) in the sixth class to 4900 frs. (\$980) in the first. Principals and teachers in colleges are paid less than *professeurs* and teachers in lycées. In some well-attended colleges, however, the salaries of the principals depend on the number of pupils, since these schools are run at their own expense and the income may reach a considerable figure.

*Cost of Secondary Education.* — Although secondary education is not free, the receipts from fees are far from sufficient to cover expenses, which in the lycées amount to about 9,000,000 frs. for the *externats*, and 8,500,000 frs. in the *internats*. The State must, therefore, intervene on behalf of the *externats*, the accounts for *internats* and *externats* being kept distinct. A boarder costs the State almost nothing, since the fees are high enough, but each *externat* student costs the Treasury at least 261 frs. (\$52.20). The state subsidy in 1910 was as follows: To supplement the receipts of the *externats* 8,400,000 frs., of the *internats* 584,560 frs. To these sums must be added various sums in aid of salaries, 5,377,650 frs.; for the allowance to *agrégés* 702,000 frs.; for general expenses 177,800 frs. If to this be added the subsidy to the colleges, which are for the most part maintained by the communes, about 6,500,000 frs., and three or four millions for national scholarships, and various expenses, the State contributes to secondary education twenty-three or twenty-four millions of francs.

*Education of Girls.* — The public secondary education of girls was established by law of Oct. 21, 1880, which may be called, after its author, *loi Camille Séc.* It was also intended to establish a woman's university and to organize a national system of education of girls by founding public institutions analogous to the lycées and colleges for boys. This was a great novelty, and possibly seemed a very bold proposition. Up to that time there was

hardly any education of women; it was provided without regular methods or definite programs and in a conservative spirit only in convents or private schools. The law of 1880, in making the education of women a duty of the State, was, at the same time, the recognition given to the rights of women and the need of education. The undertaking has been marked by success. From year to year, since 1880, the clientèle of the lycées and colleges of girls has not ceased to increase. From year to year the number of institutions established to meet the demand in the towns where no provision had yet been made continued to grow.

There are three types of institutions for the secondary education of girls: (1) national lycées; (2) communal colleges; (3) secondary courses, established by the municipalities and subsidized by the State. As a general rule, these establishments are day schools, but at the request of the municipal council boarding departments may be added to the day schools. In the Paris lycées there are no *internats*, but they are found to a large extent in lycées of the provinces. The secondary courses established in towns of lesser importance are provisional institutions, being, as it were, colleges in process of formation. Each year sees the transformation of secondary courses into colleges, or even lycées. Instruction there given must approximate as nearly as possible that of the lycées.

There are at present forty-eight lycées for girls, sixty-five colleges, and thirty-seven secondary courses. The attendance is about 35,000. At the beginning there were only 10,000; in 1901, 20,000, and in 1908, about 34,671.

*Length and Division of Studies.* — The course extends over five years, two years less than the education of boys. It is divided into two sections of three and two years respectively. The foundation for the five years' course is laid in primary classes attached to the lycées and colleges; and the course is supplemented by a sixth year, which, however, is provided in only a small number of important lycées for those girls who are preparing for the higher normal school at Sèvres.

*Administration.* — The lycées, colleges, and secondary courses are each under a directress, assisted generally by a bursar, general surveillants, and tutors, all appointed by the Minister. Further, a board of governors, consisting of the prefect, the mayor, the inspector of the academy, the directress, two municipal councillors, and two ladies, exercises supervision and control over each institution. Finally, committees of patronage, consisting of ladies only, were established in 1896 to promote entrance into the lycées and college, and to watch their progress.

The instructing staff in the lycées for girls numbers about a thousand, of whom 250 are *professeurs agrégés* in science or letters. The

rest are only acting teachers, holding only the *certificat d'aptitude à l'enseignement secondaire*. Including all the teachers of drawing, singing, etc., the teaching staff of lycées and colleges numbered, in 1910, about 1275 women. There must be added the male teachers, borrowed from lycées and colleges for boys, who have charge of some classes. But the tendency, which is increasing more and more, is to give girls only teachers of their sex.

*Curriculum.* — Instruction includes (1) morals; (2) French language, reading aloud, and at least one modern language; (3) ancient and modern literature; (4) geography and cosmography; (5) national history and outlines of general history; (6) arithmetic, elements of geometry, chemistry, physics, and natural history; (7) hygiene; (8) domestic economy; (9) needlework; (10) some notions of common law; (11) drawing; (12) music; (13) gymnastics. Optional courses in Latin have been established recently in some lycées.

"Modern language" here practically means English or German, for almost without exception every school offers both these subjects, while the Italian, Spanish, and Arabic are relatively less important than in the boys' schools. In this essentially "modern" curriculum, the "ancient and modern literature" (a study of the classic writers of Greece, Rome, Italy, Spain, England, and Germany through the medium of the French) is a manifest attempt to supply the lack of direct humanistic influence.

*Academic Rewards.* — The baccalaureate is rarely sought by pupils in the girls' lycées, nor do the studies give direct preparation for the degree, so that the girl holding the bachelor's degree is rare. But other academic rewards have been established. Examinations are held of a very friendly character, since they take place within the schools, and are conducted by examiners who for the most part are the teachers themselves. These lead up to (1) *Certificat des études secondaires* at the end of the third year; (2) the *Diploma de fin d'études*, at the end of the fifth year. This diploma is demanded of girls who present themselves at the school of Sèvres, or who are candidates for tutorial positions in lycées or colleges. But by a remarkable anomaly holders of the diploma are not eligible for positions in primary schools. A fair number of secondary school students present themselves for the examination for the primary certificate, and holding the *brevet supérieur*, they can demand employment as teachers. Those young women who desire to teach in secondary schools, once they have the diploma, must in the first place obtain the *certificat d'aptitude*, which confers the right to be appointed as acting teacher in the lycées or professor in the colleges. This certificate is for women the equivalent of the licentiate for men. The *agrégation* alone confers the right to an appointment as professor in a lycée. To be a candidate for the *agrégation*, the certifi-

cate must have been held for at least one year. A competition takes place each year before a special board in letters and science. The *agrégation* in letters includes two sections, literary and historical, while in science there are the mathematical and the natural and physical science sections. There is no special *agrégation* for women in the teaching of modern languages. The *agrégation* in German and English, which is given to men, is open to women on exactly the same conditions, but they may also present themselves for the certificate of ability to teach modern languages.

*Higher Normal School at Sèvres.* — When the law of 1880 instituted a system of secondary education for girls, there remained the task of preparing suitable teachers for them. This was provided by the law of July 26, 1882, by which a higher normal school was established for the training of women teachers. This school performs for secondary education the service which the school at Fontenay aux Roses performs for elementary education. It is a boarding school located at Sèvres. Students are admitted by a competitive examination. The length of the course is three years. At the end of the second year the students enter for the *certificat d'aptitude d'enseignement secondaire*, which is competitive; at the close of the third year they present themselves for the competitive examination for the *agrégation*. Instruction is throughout given by male professors, who are selected from the members of the faculties and the Paris lycées and who have the title of *chargés de conférence*. The Higher Normal School is provided for in the State Budget with sums of 155,200 frs. (\$31,040) for salaries, and 101,500 frs. (\$20,300) for equipment. Only twenty pupils are received each year, in two sections, letters and science. This number is too small to meet the demand for teachers. But the supply of teachers is increased by the number of women who do not enter Sèvres, but prepare themselves elsewhere for the *certificat d'aptitude* and for the *agrégation*, either in the Faculty of Letters or Science, or in private institutions, such as the *Collège Sévigné* or the *Cours de la Mutualité Maintenon*, both in Paris.

*Cost of Education.* — Secondary education of girls is not free, any more than that of boys. The fees cover the expenses to some extent. The communes and departments also share in the cost. But the State intervenes with large subsidies, inscribed annually in the budget. In 1910 this subsidy rose to 1,536,500 frs. (\$307,300) for the lycées, to 723,920 frs. (\$144,784) for the colleges, to 227,950 frs. (\$45,590) for the secondary courses. To this must be added about one million francs toward salaries, payment of substitutes, renewal of equipment, etc. The whole sum expended by the State was three and a half million francs (\$700,000).

*Salaries.* — The salaries in the departments are fixed as follows: —

In the lycées:—

CLASS		IV	III	II	I
		<i>frs.</i>	<i>frs.</i>	<i>frs.</i>	<i>frs.</i>
Directress	<i>agrégée</i> . . . . .	5000	5500	6000	6500
	<i>licenciée</i> or <i>certifiée</i> . . . . .	4500	5500	5550	6000
	<i>brevétée</i> . . . . .	4000	4500	5000	5500
Bursars . . . . .	2400	2800	3200	3600	
Professors ( <i>agrégés</i> ) . . . . .	3000	3400	3800	4200	
Acting teachers . . . . .	2500	2800	3100	3400	
Primary teachers . . . . .	1500	2100	2400	2700	
Tutors (with rooms, but not board) . . . . .	1500	1800	2100	2400	
Teachers of drawing . . . . .	—	1800	2100	2400	
Acting teachers of drawing . . . . .	—	—	—	1600	
Teachers of needlework . . . . .	1600	2100	2400	2700	
Teachers of singing . . . . .	1000	1400	1600	1800	
Teachers of gymnastics . . . . .	—	1200	1400	1800	

In the colleges:—

CLASS		IV	III	II	I
Directress . . . . .	2600	3000	3500	4000	
Professors . . . . .	2500	2800	3100	3400	
Acting teachers . . . . .	1800	2100	2400	2700	
Primary teachers . . . . .	1600	1800	2000	2400	
Teachers of drawing . . . . .	—	1800	2100	2400	
Acting teachers of drawing . . . . .	—	—	—	1600	
Teachers of needlework . . . . .	1600	1800	2000	2400	
Teachers of singing . . . . .	1000	1200	1400	1600	
Teachers of gymnastics . . . . .	—	1200	1400	1600	
Surveillantes of the day schools (with rooms but not board) . . . . .	1400	1600	1800	2200	

In the Paris lycées salaries are as a rule higher by 500 frs.

**Conclusion.**—Secondary education in France, both for boys and girls, is in a satisfactory condition. Within the last twenty years a very liberal discipline has been introduced into the lycées and colleges, which has made school life much pleasanter. It cannot now be said that these schools resemble barracks. Formerly riots were common enough in the lycées; to-day they are a thing unknown. The vacations (two months in August and September, two weeks at Easter, etc.) are frequent enough to allow the pupils to rest and to revive their ardor for work. The studies show sufficiently good results, although there was much talk recently of an imaginary crisis in French education. Greek and Latin alone are losing ground; but in their place modern languages and scientific studies have gained rapidly.

**HIGHER EDUCATION.**—**Historical.**—The reputation of the University of Paris in the Middle Ages, when thousands of students flocked to Mt. St. Geneviève, is well-known, as also the success of some provincial universities, such as Montpellier. But gradually these institutions declined and became nothing more

than shadows of their former selves, without exercising any real influence. In fact, it may be said that they no longer existed, when they were abolished at the Revolution. They were not reëstablished until 1806. The decree of Napoleon of March 17, 1808, for the creation of the University of France divided the country up into twenty-seven academies, and established five different faculties, — theology, law, medicine, science, and letters. Each academy was to have a faculty of letters and a faculty of science. But these faculties, established near each principal lycée, were very poorly equipped with a grant of from 500 to 1000 francs for each, and a few professors, borrowed partly from the local lycées. The faculties of letters included, in the provinces, the professors of literature in the lycées and two other professors, in Paris three professors from the College of France and three professors of literature from the lycées. As a matter of fact, the chief task of the faculties of letters and science was the conferment of the three university degrees of bachelor, licentiate, and doctor. The Restoration considered that this was excessive, and Louis XVIII suppressed at one blow seventeen faculties of letters on Oct. 31, 1815, and three faculties of science. A few were reopened under the July Monarchy, notably Bordeaux, Lyons, Montpellier, and Rennes in 1838, Aix in 1846, and Grenoble in 1847, while the condition of all was improved by the addition of new chairs.

In an article of 1864 Renan severely criticized the condition of higher education, and without denying that there had been brilliant and glorious periods, as in the time of Cousin, Villemain, and Guizot, he deplored the sacrifice of science "to oratorical exercises." He pointed out that there was an "epidemic of brilliant wit" among the professors, and proved that their courses were mainly nothing but brilliant expositions, recitations in the style of declamation and of the rhetoricians of the Roman decadence, that there was not found among them "any movement productive of research." Finally he charged them with not creating scholars, for the good reason that they had none, at any rate in the faculties of letters and science, and were reduced to poring before an audience of idlers and amateurs. He concluded by saying that, compared with the German universities, the faculties of France were in a shameful condition of inferiority. Things have changed since 1864, and the French universities, revived by the law of July 10, 1896, bring honor to higher education and to their country. The way had been paved to their reconstitution for several years. Since 1885 various decrees had established a general council of faculties in each capital of the academies, charged chiefly with the task of supervising the observance of regulations in studies and of establishing some coördination between the different courses and studies of

the faculties and schools for the improvement of education and in the interest of the students. This is exactly the part played at present by the university council.

**Present Conditions.** — The law of 1896 established fifteen universities, and a sixteenth is about to be established in Algiers. It was at first thought that it would only be appropriate to give the title of university to a group of the most important and complete faculties located in the largest cities. Such a procedure would have caused dissatisfaction to other towns, and would have deprived them of faculties which they had had for a long period. It was accordingly decided to establish a university for each academy, except at the small academy of Chambéry, which had no faculties and only a preparatory school for higher instruction in letters and science. The universities are not yet all provided with complete faculties. There are only two, letters and science, at Besançon and Clermont-Ferrand. There is no medical faculty at Aix-Marseilles, Caen, Dijon, Grenoble, Poitiers, Rennes. There are thus only eight complete universities, Paris, Bordeaux, Lille, Lyons, Montpellier, Nancy, Toulouse, and Algiers, but in those which have no faculty of medicine there is a preparatory school of medicine and pharmacy, where students commence their courses and pass the first examination. The schools of medicine and pharmacy are either complete or preparatory. There are two complete medical schools, at Marseilles, and at Nantes, attached to the University of Rennes. They are distinguished from the preparatory schools in giving a more complete training. There are twelve preparatory schools: Amiens, Angers, Besançon, Caen, Clermont, Dijon, Grenoble, Limoges, Poitiers, Rheims, Rouen, and Tours. The University of Paris has in addition to the four faculties a higher school of pharmacy, but in the provinces this subject is given in the schools of medicine, which are on this account called "mixed faculties."

The universities are established in capitals of the academies; the University of Aix-Marseilles alone does not have a single seat, for its faculty of science and school of medicine and pharmacy are located at Marseilles, the faculties of law and letters at Aix. Generally the universities are located in neighboring or even contiguous buildings, so that the four faculties, which should have a common spirit, may form one whole materially. There are striking exceptions; thus at Paris the Sorbonne only houses under the same roof the faculties of letters and sciences, and a few minor departments, while the faculties of law and medicine occupy separate buildings. Most of the universities, thanks to competition between the State and municipalities, are provided with beautiful buildings, some old, repaired and enlarged; others entirely new and truly scholastic palaces.

*Growth of the Universities.* — The universities have made a remarkable increase in the number of students within recent years, being about 30 per cent. In January, 1903, there were 31,589 students; in 1909 there were 40,961 male and female students, for the universities are all open to women. The increase is particularly noticeable in the faculties of law, science, and letters; in law there were in 1909, 17,000 students, an increase of 5000, or 40 per cent, over 1905; in science 6408 students, an increase of 1360, or 27 per cent; in letters 6216, an increase of 1992, or 47 per cent. Only the faculties and schools of medicine and pharmacy either fail to show an increase or have actually decreased in numbers. This is due to overcrowding in the professions for which these establishments prepare.

The University of Paris alone has an attendance of more than a third of the students of higher education, 17,512 in January, 1910. In point of numbers, the university stands the first in the world, and surpasses the University of Berlin, which comes second, by several thousands. She is also far wealthier than her German rival, spending seven millions of francs annually, or two millions more than Berlin. These resources come (1) from the state subsidy of 4,000,000 frs. for salaries, and 600,000 frs. for equipment, (2) from her own revenues of more than two millions. Her library contains about 600,000 volumes. The University of Paris naturally offers the largest opportunities in all kinds of instruction. The faculty of law has 33 professors and 2 *agrégés*. The faculty of medicine has 35 professors and 40 *agrégés*, more than 15 superintendents, 55 laboratory and clinical aids, and a number of assistants in anatomy. In the faculty of science there are 23 professorial chairs, 15 *cours complémentaires*, 13 *conférences*, 20 directors, or laboratory assistants, 59 preparators, with a number of mechanics and heads of workshops. The faculty of letters has 33 chairs, 19 *cours complémentaires* and 16 *conférences*. The higher school of pharmacy, an integral part of the university, has 12 professors, 9 *agrégés*, and 35 superintendents and preparators. Without including the leaders of the *conférences*, *agrégés*, and acting professors, the University of Paris has 149 professors, who may with justice be said to represent all that is to be known in human knowledge.

The provincial faculties do not fare so well. The courses are almost as numerous; but it is impossible to enter into details of each. The number of professors for all the universities together is as follows: faculties of law, of which there are thirteen (Paris, Algiers, Aix, Caen, Bordeaux, Dijon, Grenoble, Lille, Lyons, Nancy, Poitiers, Rennes, Toulouse), with 164 professors, 20 *agrégés*, 163 *cours complémentaires*; faculties of medicine, of which there are seven, with 133 professors, 92 *agrégés*, 35 *cours complémentaires*, 53 directors and assistants, 54

heads of laboratories and clinics, and a large number of preparators and assistants in anatomy; faculties of science in all the universities, with 144 magisterial chairs, 14 *cours complémentaires*, 51 *conférences*, 49 laboratory superintendents, 115 assistants; faculty of letters, one for each university, with 142 magisterial chairs, 18 *cours complémentaires*, and 50 *conférences*.

*Appointment of Professors.*—The professors in the universities are appointed by the Minister of Public Instruction. They must hold the doctorate in their respective faculties. In addition, in the faculties of law and medicine the professors must have obtained the *agrégation* in law or medicine in competitive examinations. This condition was also imposed for a time on professors in science and letters, and the *agrégation* of the faculties was the usual qualification for all candidates for positions in higher education, but this rule has fallen into disuse, and in science and letters the doctorate is the only degree expected, as also in the case of rectors. But appointments are not made directly to professorships. In the faculties of law and medicine the teacher enters on his career as *agrégé*, in science and letters as acting teacher or director of *conférences*, with a lower salary than the professors. Appointments to professorial chairs are not made before the age of thirty. When a chair already in existence is to be filled, the council of the faculty, and, after it, the council of the university, present a list of nominations, containing at least two candidates, to the Minister for his selection.

*Salaries.*—The professors of the University of Paris are divided into two classes, and receive from 12,000 frs. to 15,000 frs. (\$2400–\$3000). In the provinces the professors are divided into four classes, paid from 6000 to 12,000 frs. (\$1200–\$2400). The deans receive an additional salary in Paris of 3000 frs. (\$600), and elsewhere of 1000 frs. (\$200). An *agrégé* in law receives 7000 frs. in Paris and 3000 frs. in the provinces; in medicine 3000 frs. in the provinces and 4000 frs. in Paris. Promotions from class to class are made on the first of January each year, some by seniority, some by selection on the recommendation of the Minister to the Consultative Committee (section for higher education). The list of recommendations must contain at least twice the number of names required for promotion.

The age for retirement is seventy for professors of the faculties, seventy-five if they are members of the Institute. They may be retained in service, but not on the active list, after consultation with the permanent section of the Superior Council for Public Instruction.

*Number of Students.*—The number of French and foreign students, male and female, on Jan. 15, 1910, was 41,014, distributed as follows: 16,915 in law (the best attended faculty); 8029 in medicine; 6287 in science; 6363 in letters; 448 in the mixed

faculties and the higher school of pharmacy; and 2002 in the schools of medicine and pharmacy. The male foreign students numbered 3114, as against 33,770 French. The enrollment of women was 3830, of whom 2033 were French and 1797 foreign. The distribution of universities was as follows: Lyons, second to Paris, 2922; Toulouse, 2828; Bordeaux, 2552; Montpellier, 1965; Nancy, 1899; Lille, 1675; Rennes, 1602; Algiers, 1442; Aix-Marseilles, 1236; Grenoble, 1156; Poitiers, 1111; Dijon, 992; Caen, 722; and finally those universities with but two faculties, Clermont, 275, and Besançon, 268.

*Organization.*—Each faculty is under the direction of a dean, selected by his colleagues and ratified in his appointment by the Minister. He is provided with an assistant. The schools of medicine have a director at their head. The dean presides at the councils and meetings of the faculty where interests and matters proper to it are discussed. But the establishment of a university would serve no purpose, if a common life and a close sympathy between the different faculties were not established. There is, accordingly, a university council, which meets frequently for the discussion and investigation of all general questions. It is composed of the rector, the president, the deans, directors of medical schools, legal representatives, the director of the observatory, if there is one, and two professors of the faculty, elected by their colleagues. Up to 1896 the academic councils decided disputes and questions of discipline, which referred to higher public instruction. The law of 1896 transferred this power to the university council, from whose decisions an appeal lies to the Superior Council of Public Instruction. The university council may make definite statutes, may deliberate, or may give its advice on matters submitted to it. It may pass statutes on the following subjects: coordination of courses, conferences and practical work, which are recommended each academic year by the faculties; on the regulations for free courses; on the dispensation of students from fees; and on the vacations. It may deliberate on the establishment of courses out of the funds of the university; on scientific degrees which can be created apart from the state degrees, etc. The decisions, however, are not binding, as would be the decision of the Minister in similar cases. Its advice may be given on questions submitted by the Minister, on the budget of the faculties; on the creation, transformation, or suppression of chairs paid out of state funds; on regulations dealing with common service; library, cleaning, heating, maintenance of buildings, examination expenses, etc. Thus it is obvious that the universities only enjoy a relative autonomy, the State always retaining some controlling power.

*Degrees and Diplomas of Higher Education.*—The degrees of bachelor, licentiate, and

doctor are conferred by the faculties. In 1905-1906 the University of Paris created 300 doctors in law, 500 in medicine, 30 in science, and 30 in letters. The faculty of law grants two doctorates: (1) in legal sciences, (2) in economic sciences. But in addition to the state degrees, the faculties of science and letters grant special diplomas, called diplomas of higher studies: in letters there are diplomas in philosophy, history, geography, classical languages, modern foreign languages; in science there are diplomas in mathematics, physical science, and natural science. The faculty of science also grants a certificate of P.C.N. (Physical, Chemical, and Natural Science), which is required for entrance into the medical courses, while for the other faculties the only admission requirement is the baccalaureate in secondary education. The faculty of law gives the *certificat de capacité en droit*, which is required for the profession of attorney. For the medical faculty there is a diploma in dental surgery, and of first and second-class midwives. The courses in pharmacy, which are preceded by a compulsory stage of three years in the office of an apothecary, lead to the title of apothecary of the first class, and, on presentation of a thesis, to that of superior apothecary.

The university degrees are conferred in the name of the State, but since their establishment the universities have instituted a large number of degrees, in conformity with the decree of July 21, 1897. Several have created the degree of university doctor, which does not confer the same rights, although the candidate has passed the same conditions as a state doctor; such a doctor, for example, cannot practice medicine in France. All the universities have established diplomas and certificates, dealing with special studies and sought by different classes of students. Thus the University of Lyons, which ranks among the first in number of students and the rich variety of courses, gives more than ten diplomas of the following type: pharmaceutical diploma for foreigners; diplomas in French, also for foreigners; brevet in electrotechnical studies; diploma in agricultural studies; certificates for notaries; diploma for higher pedagogical studies; diploma in Chinese; certificate in hygiene; brevet in the technical studies of industrial chemistry; certificate of higher studies for young women.

*Student Expenses.*—A complete course in the faculty of medicine costs a student 1860 frs. (\$372), made up as follows: baccalaureate of secondary education, 140 frs.; certificate of P.C.N., 305 frs.; sixteen registrations and library privileges, 520 frs.; laboratory fees, 210 frs.; seven examinations or tests, 220 frs.; seven *certificats d'aptitude*, 175 frs.; thesis, 100 frs.; *certificat d'aptitude* for the thesis, 40 frs.; diploma, 140 frs. The expenses in the faculties of law and science are about the same; in letters they are considerably less, not being more than 550 frs.

*Credits.*—The students must first of all matriculate; the matriculation is valid for one year, and may be performed at any time in the academic year, the dues being 20 frs. Secondly, they must register at definite times each term. On registering for the first time, they must produce their baccalaureate diploma, or, in default, and in certain faculties, with the authorization of the Minister, they must show the equivalent requirements mentioned in the decree of July 28, 1910. Foreign students may obtain credits for the baccalaureate by producing a degree or definite title or evidence of the studies pursued by them in the country of origin.

*Scholarships.*—University education, like secondary, is not free, but the State has established a certain number of scholarships relieving students from fees, and gives them free access to the faculties. In 1910 there were set aside in the budget for this purpose 262,000 frs. for provincial universities, and 114,000 frs. for the Paris University. These scholarships are given either to candidates for the licentiate or for the *agrégation* in those universities which are in a position to prepare for the examinations. There is further set aside a sum of 106,000 frs. for scholarships for research, travel, and study in a foreign country. Finally, each university gives to a certain porportion of the students dispensations from fees for registration and courses.

*Private Resources of the Universities.*—The law of 1896 gave the universities the rights of a civil person, that is, the right of accepting gifts and legacies, of holding private property, and of administering it without restrictions. Each university has a budget in which are included the receipts from fees for courses, registration, library and laboratory fees paid by the students in accordance with the regulations. The income from this source may be spent on the following objects: expenses for laboratories, libraries, and collections; creation and maintenance of buildings; establishment of new courses; grants in the interest of students, as, for example, subsidies to student associations. The French universities have not, up to the present time, met with such generous donors as those of the American universities, but a good beginning has been made, and at the University of Paris the names of benefactors are inscribed on a marble tablet; while Lyons, Montpellier, Bordeaux, and others have also received important gifts.

*State Expenditure.*—The French universities do not enjoy complete financial autonomy, and in fact they could not exist on their own resources. The contribution of the State toward their expenses is considerable, the salaries, for example, coming from this source. But the State, on the other hand, benefits from certain sums which are deposited by the universities, and cannot be freely disposed of by them. According to Article IV of the law of

1896, "Fees for examinations (for baccalaureate, licentiate, and doctorate), the *certificats d'aptitude*, diplomas or titles, paid by candidates for the degrees or titles established by the law, shall continue to be collected for the benefit of the Treasury." In 1907 the receipts of the State from this source amounted to 5,184,775 frs. (\$1,036,955).

The University of Paris is provided for in the budget to the extent of 3,920,199 frs. (\$784,039.80), for salaries of professors and assistant instructors, library, other services, and payment of minor officials. The cost of the provincial universities to the State is 7,520,580 frs. (\$1,504,316). To this must be added the expenses for equipment, which amounted to 2,229,827 frs. (\$445,965.40). (The figures here given are from the budget for 1910.)

*École pratique des hautes études.*—This school was established in 1885 for the purpose of providing the practical work which would establish and extend the theoretical instruction. It includes five sections, (1) and (2) mathematical, physical, and chemical science; (3) natural sciences; (4) history, philology, and architecture; (5) religious sciences. This school is a part of the University of Paris, from which it borrows a large number of its professors, who hold the title of *maîtres de conférences*.

*Higher Normal School.*—This school, for a long time independent, is now attached to the University of Paris. Its director, at present M. Lavoisier, is a professor in the faculty of letters. The students attend the courses at the Sorbonne. A special competitive examination is held each year to recruit students for both sections, letters and science, of the school, which is free.

*Observatories.*—Instruction and research in astronomical studies are given in the eight observatories of Paris, Besançon, Lyons, Bordeaux, Marseilles, Toulouse, Puy de Dôme, and Pic du Midi. The observatories are under a director and an administrative council; that at Paris is an independent institution; those in the provinces are parts of the universities in whose territory they are located.

*Collège de France.*—Established by Francis I about 1530, with only two chairs, Greek and Hebrew. In 1545 there were already twelve professors, or royal lecturers, as they were called; at present there are forty-five. It was here that Claude Bernard and Renan, to mention these two names only, taught. The institution is entirely independent and distinct from the University of Paris. It stands for scientific freedom. It is directed by an administrator selected by the professors, who are themselves appointed by the Minister on the recommendation of the professors in office and of the academies of science and moral and political sciences of the Institute of France. The courses are very varied, and are given in the form of public lectures. The salary of

the professors is 10,000 frs., while there is set aside in the budget for salaries and equipment in the college about 6500 frs.

*Other Institutions.*—Among those institutions which should be included in the system of higher education are the following; *l'École des Langues Orientales Vivantes*; *l'École des Chartes*, which gives a training in the keeping of archives and paleography; the Museum of Natural History, where instruction in all branches of natural science, and particularly in their application to industrial and commercial arts, is given. These institutions are independent, and are not connected with the University of Paris. Further, the following special government schools may be considered under higher education: *École Polytechnique* for artillery officers, engineers, etc.; the military school at St. Cyr (see MILITARY EDUCATION); the naval school at Brest (see NAVAL EDUCATION); the school of roads and bridges; the school of mines; and the central school of arts and manufactures for training civil engineers, etc. (see TECHNICAL EDUCATION).

*Private Higher Education.*—The freedom of teaching, recognized by the laws, extends to higher education just as to the other two branches. This, however, has only been in existence since 1875, when the establishment of a free university was about to be authorized with power to grant state degrees. But the law of March 18, 1880, decided that a free institution could on no account assume the name of university, and that the granting of degrees was exclusively reserved to the State. Those students in free faculties who desire to obtain degrees are subject to the same rules of study and academic qualifications as the students in the state faculties, and like them they must present themselves for examination before the state professors. Neither associations nor individuals have availed themselves much of the freedom given to them. The Catholic Church, however, has established a number of faculties. There are at present twelve free faculties: five of law, at Paris, Marseilles, Angers, Lille, and Lyons; one mixed faculty of medicine and pharmacy at Lille; three faculties of science, and as many of letters at Angers, Lille, and Lyons. In addition faculties of Catholic theology have been established at Lille, Angers, Toulouse, and Paris. There is also at Paris a free school for higher scientific studies.

*Influence of the Universities.*—The French universities do not labor for France alone. The number of foreign students is continually increasing. In a few universities holiday courses have been organized especially for these, which are very well attended, notably at Grenoble, where as many as 589 students have been enrolled. At Lyons and elsewhere special certificates have been instituted for foreigners who regularly pursue an ordinary course or make progress in the studies specially estab-

lished for them. Further, American professors have delivered lectures in their own language at Paris, and several provincial faculties have their own foreign lecturers. Finally, without mentioning the schools of Rome, Athens, and Cairo, the French universities reach out to neighboring countries by means of dependent institutions. Thus Grenoble has established the Institute of Florence, where Italians may study French language and literature, and Frenchmen may study Italian language and literature. In the same way the universities of Bordeaux and Toulouse, bordering on Spain, are about to establish a French Institute and a school for higher Spanish studies. A Bureau of Inquiry, established in 1903, exists at the Sorbonne to give information on the means for pursuing all kinds of studies in Paris.

**FRANCE, EDUCATION IN THE COLONIES OF.**—The colonies and dependencies of France, exclusive of Algeria and Tunis, are roughly estimated to comprise an area of 3,820,000 square miles, with a population of 49,000,000. Algeria, though called in France "the great colony," is now administered as an integral part of the State, and Tunis is under the ministry of foreign affairs. The colonies proper may be most conveniently grouped by their continental relations, as in this survey.

Widely separated as these possessions are, representing totally different conditions as regards both the native inhabitants and the French settlers, or colonists, they have been brought under one general administration, following the usual centralizing policy of the French government. A separate ministry for colonial affairs was created in 1894, and a general plan of local administration has since been pursued in the several colonies. There is a resident governor, or other chief executive, in each, who is assisted by an elected council, representative government being encouraged where circumstances permit. The older colonies have representation in the French legislature. Réunion, Martinique, and Guadeloupe send each one senator and two deputies; French India, a senator and a deputy; Senegal, Guiana, and Cochin-China, a deputy each. The remaining colonies are represented only in the superior council of the ministry, which consists of the colonial representatives and other persons appointed on account of their special knowledge of the interests to be considered.

The course of modern education in all these colonies has been practically the same: the Church, or more particularly, the teaching

orders (*congréganistes*) were the pioneers in the work, and, later, the official, secular system was introduced, and tends, as in France itself, to displace the clerical system. In the later acquisitions, and particularly in the Asiatic colonies, India, Cochin-China, etc., the influence and instruction of the teaching orders have greatly promoted the interests and prestige of France.

**The American Colonies.**—Prior to 1832 no effort was made by the French government to provide for education in the French Antilles, Guadeloupe and its dependencies, and Martinique. Schools were, however, maintained by the teaching orders, and in these free instruction was given. In 1840 a subvention of 200,000 frs. (\$40,000) was allowed from the French treasury for education in Martinique; and a decree of April 27, 1848, established gratuity of instruction and required each commune to maintain two schools, one for boys, the other for girls. A similar decree was issued for Guadeloupe, and, as the slaves were freed in the same year, the need of school provision became urgent. Practically the teaching orders controlled the work until the French Republic was firmly established. After 1880, following the course of events in France itself, the laws that rendered the French schools secular, gratuitous, and obligatory upon the communes, were extended to these islands. By a decree of July 24, 1895, the direction of education in each was committed to a chief officer of public instruction, subject only to the Governor-General. Since that date, public communal schools have multiplied, and clerical schools have declined. Two public normal schools were established in Martinique in 1883, one for girls, annexed to the boarding school for girls at St. Pierre; the other for boys, annexed to the lycée (classical school) at the same place. Higher education is represented by a law school at Fort-de-France. Guadeloupe has, also, a normal school for boys. According to the latest official statistics, the attendance at the different classes of schools in 1909 was as follows: Martinique (population 203,000), primary schools, 13,878 pupils; secondary, 559; normal, 23; law school, 150; Guadeloupe (population 182,000), primary schools, 12,282 pupils; secondary, boys 263, girls 165; total, 728.

The progress of education in French Guiana has been adversely affected by the chief industry, mining, in which the majority of the colonists are engaged, and by the peculiar conditions of the penal settlement; as in Martinique and Guadeloupe, the French laws governing public instruction have been applied, and in 1909 there were twenty-four primary schools in operation, with about 2300 pupils, a little less than 6 per cent of the population. In Cayenne, a college is maintained, and also a local museum and public library.

The small islands of St. Pierre and Mique-

lon are well supplied with primary schools, and in 1909 reported 495 pupils in public schools, 337 in private schools, and 136 in infant schools, or a total of 968 children under instruction, which was about 10 per cent of the population.

**The African Colonies.**—As regards the African possessions, the greatest advance in education has been made in those that have been longest under French dominion, namely Senegal, Réunion, and Madagascar. The four municipal communes of Senegal, St. Louis the capital (population 24,600); Dakar, a fortified naval station (population 24,800); Rufisque (population 12,446); and Gore (population 1500) have primary schools modeled on those of France, and following, so far as possible, the same programs. At St. Louis a secondary school is maintained, to which pupils are sent from all the West Africa colonies, and a normal school for the training of native teachers; at Dakar there is a technical high school, common to all the colonies. The natives of the four towns named are French citizens, and the main purpose in their education is to make them serviceable to the administration as agents in the efforts to extend modern ideas among the surrounding people. Special efforts have recently been made to assure a steady attendance of 100 students at the normal school, thus providing for twenty-five graduates a year, prepared to carry on the work of civilization in the villages.

The colonies of West Africa include, in addition to Senegal, Upper Senegal and Niger, French Guinea, the Ivory Coast and Dahomey, with a population estimated at 11,000,000 and upwards. By a decree of 1903, an Inspector-General of Education was appointed for the entire territory with headquarters at Dakar. The Governor-General has since appointed several commissions to inquire into the condition of education and advise as to means for extending the school provision among the natives. This is a difficult problem, as about 70 per cent of the people are Mohammedans and the remainder pagans, excepting a small body of Roman Catholics, numbering about 15,000, and 3500 Protestants.

The total number of French schools reported in Senegal in 1908 was thirty-nine, viz. thirty-five public, with 3608 pupils, and four private clerical schools with fifty-three pupils. In French Guinea, in the same year, there were twenty-two public schools, with 1304 pupils, and two clerical schools, with 67 pupils.

In Upper Senegal and Niger there were fifty public schools, with 1639 pupils, and two clerical schools, with 95 pupils. In the entire territory about 10,000 boys were receiving instruction in French schools. The number of Mohammedan schools in this extended region is unknown, but they greatly outnumber the French schools. In the four municipal communes of Senegal there were reported 117 schools of this class in 1902, with 2127 pupils, including 484

girls. Excepting in one higher school at St. Louis, the instruction given was limited to citations from the Koran and very elementary accounts.

The need of extending a knowledge of the French language among the natives is urgent, since contact with the dominant people has inspired them with the desire for written language; and having none of their own they are turning to the Arabian, and thus coming more and more under the influence of the Mohammedan faith. This is a cause of anxiety to the French authorities, who, though entirely neutral in respect to religion, have reason to apprehend trouble from the fanatical spirit of Moslem converts.

The history of French schools in the island of Madagascar dates from 1880, in which year the *Frères des Écoles Chrétiennes* opened their first school in the island. The mission society of London had about 1200 schools in the island at that time, and at Tananarive had established a college and a normal school. These mission schools, excepting the college, which had been closed, were taken over by the Paris society of evangelical missions in 1897. They are now known as French Protestant schools. The work of the Christian Brothers, interrupted by the Franco-Hova war, 1882-1884, was resumed again, and has steadily progressed.

Other missionary societies, the Friends, Lutheran, etc., have carried on the work of instruction and evangelization in the island; and in 1895 it was estimated that the greater part of the central tribes, including the Hovas, had been Christianized. The Christian population included 450,000 Protestants, and 50,000 Roman Catholics. The purpose of the government to establish a system of public secular schools was indicated by a decree of Dec. 11, 1895, and in 1904 a decree was issued giving formal organization to the service. The schools for the French and other European colonists are maintained on an independent basis, and are classified like those of France. The schools for the natives are primary, regional, and higher. The primary schools are attended by boys and girls from eight to thirteen years of age, the obligatory school ages. The course of study includes the native tongue and the French, and the elements of arithmetic, hygiene, agriculture, history, geography, and drawing. Each school has a garden, if possible, in which the boys work an hour and a half daily; the girls employ the same time in sewing and cutting out garments. In addition to the master, a woman assistant is employed in every school to teach sewing and domestic arts. The regional schools are established at important centers. In their complete stage they include a general course of study, covering two years, and an industrial or technical course of three years. The general course prepares for admission to the normal school. The headmaster of a regional school is always a Euro-

pean; the assistant professors and teachers may be natives. The class of higher schools includes a normal school, school of commerce and administration, higher technical school, and school of medicine. For the direction and control of this system the island is divided into four circumscriptions; the official staff includes one general director, two inspectors of primary instruction (European), and three native inspectors.

The actual development of this system is shown by the latest official statistics, which bring the record to 1909. Estimated native school population, 320,000 (170,000 boys, 150,000 girls); number of schools: 389 public, with 31,736 pupils; 301 private, with 24,329 pupils. In all these schools the teaching of the French language is obligatory. The public schools included seven completely organized regional schools and two having only the general course, also five industrial schools for girls. The number of French, or other European, children of school age was estimated the same year at 1875 (999 boys, 876 girls). All of these were in attendance upon urban primary schools, or in secondary schools maintained at Tananarive.

The island of Réunion is one of the earliest colonial possessions of France, the occupation dating from 1767. Education has followed there the same course as in Martinique and Guadeloupe, the French laws regulating public instruction having been extended to the colony in 1890. In 1909 there were 122 public primary schools in the island, with 216 teachers (104 men, 112 women) and 9206 pupils. Of the latter 4428 were in schools for boys only; 3962 in schools for girls only, and 816 in mixed schools. There were also thirty-nine private schools, classified as follows: secular schools, thirteen, with 38 teachers and 611 pupils; clerical schools, twenty-six, with 51 teachers and 3488 pupils (1023 boys, 2465 girls).

At St. Denis there is a lycée for boys, to which is annexed a normal course for young men intending to be teachers. A course in manual training is also maintained, and special efforts are being made to increase the provision for technical instruction in the island.

No attempt has yet been made to establish a system of public instruction in the French Congo region; mission schools numbering forty-three for boys and ten for girls are reported, with about 3500 native pupils.

One of the most important institutions established by the French in West Africa is the school for the sons of chiefs, founded at Kayes on the Senegal River in 1886. In addition to the three grades of an ordinary primary school, *i.e.* elementary, intermediate, and higher, there is a technical department, which has been in operation since 1903. This department is provided with workshops, and is in charge of special professors. The pupils who live in the institution are sons of chiefs and dignitaries,

and attend the school from the ages of seven to fifteen years. The general course of study prepares for the technical department, which draws pupils also from the several regional schools. This department is equipped for work in wood and iron, telegraphy, and training for medical assistants and for agriculture. The young men who have passed through the school exercise great influence upon their native communities, and are also well fitted for posts in the public service.

In the colonies of Australasia and Oceania little progress has been made in the establishment of public schools, but private clerical schools are aided by the local authorities. At Noumea, New Caledonia, there is a college with general and technical departments, and at Yahone an agricultural school. At Papeete, the chief town of the island of Tahiti, there are six public primary schools and a normal school.

**The Asiatic Colonies.** — The French colonies in Asia consist of five dependencies in India, of which the chief is Pondicherry, and French Indo-China. The latter includes five states: Annam, Cambodia, Cochin-China, Tonking, and Laos, with an estimated population of 18,230,000. The territory of Kwang-Chau-Wan on the coast of China was leased from the empire in 1899, and placed under the authority of the Governor-General of Indo-China. The development of modern secular education in this vast region was a feature of the colonial policy advocated by Jules Ferry during his brief term as Minister of Foreign Affairs (1883-1885), and practically attempted by Paul Bert, who was Governor-General in Indo-China in 1886. In respect to the territory as a whole, the purpose thus brilliantly inaugurated has never passed beyond the theoretical stage, but it has led to some notable experiments in education which illustrate both its underlying principles and their adaptations to oriental conditions. The governor of each colony has charge of education in his own province, and appoints the supervisor and the teaching personnel. No one is admitted to the service who is not provided with a teachers' diploma or a university degree. The men teachers in the schools for Europeans and the principal teachers in the schools for the natives are drawn from France; the women teachers, as a rule, from the resident population.

The endeavor to instruct the natives through the sole medium of the French language, and in entire independence of the ancient system of education, has not proved satisfactory, and in 1906 was definitely abandoned. This change was due in part to the effect of the Russo-Japanese war, which impressed the native mind with the value of western learning and the intellectual superiority of the Japanese. The importance of fostering this awakened interest was fully appreciated by the French authorities; at the same time they desired to guard against ad-

verse influences and superficial training, and to enlist the support and sympathy of the élite class of the native population, who still hold to the traditional culture of the Orient.

Under these circumstances the Governor-General of Indo-China took the lead in the adoption of a reformed system of education, of which the main features are as follows: development of the modern and the ancient learning from a common basis, designated as education of the first degree. To this succeeds education of the second degree, followed by the third degree. Each of the two higher degrees comprises two sections, the one traditional, the other Franco-Annamite. The programs of the two sections include subjects common to both. The mandarins charged with the traditional instruction are subject to the local authorities, and it is proposed to raise their salaries, as rapidly as possible, to the level of those of the French teachers. For instruction in the elements of arithmetic, geography, physics, chemistry, and hygiene, the maternal language of the natives is employed instead of French. Native teachers are eligible to the inspectorate, and several candidates are making special preparation for this branch of the service. In view of the passion for civil appointments and the abuse of examinations under the oriental system, it is decreed in French Indo-China that after 1912 persons above thirty years of age shall not be admitted to the literary examinations of the higher degree of the traditional learning.

Theoretically the new system has been adopted for the five states of Indo-China, but it has been most fully applied in Tonking. Here the elementary stage of the course of instruction is carried out in the schools of the larger villages; the course of the second degree is maintained at the chief places of Phu and of Huyen, divisions comparable to the departments of France; the course of the third degree is given at the chief place of each of the fourteen provinces of Tonking, the section of the traditional instruction being conducted at the school of the Mandarins (*Doc-hoc*), and the modern section at the Franco-Annamite school. An examination is held at the completion of each section of the course, and marks the end of the traditional course of study. In deference, however, to the customs of the people, two competitive literary examinations are held subsequently; the first of these takes place three years after the completed course of study, at the chief places of Tonking and Annam; the second examination occurs after a second interval of three years, at Hue, the capital of the ancient empire of Annam. The laureates of the first competition receive the degrees of *Cu-nhon* and of *Tutai*. These fortunate ones, if under the age of thirty years, are eligible for the second examination which secures the degrees of *Tien-Si* and of *Pho-bang*,

which are required for the higher positions in the native administrations.

The students who complete the third degree of the Franco-Annamite instruction are prepared for an advanced course, which for the province of Tonking is given at the *Collège du Protectorat*, situated at Hanoi. This instruction represents the highest type of French schools in the Orient. The course of study is arranged in two cycles. The first cycle covers three years, devoted to general studies corresponding to those of the higher primary schools of France, with the addition of the study of Chinese characters. An examination is held at the end of the course which entitles the student to the certificate of "the complementary course."

The second cycle, covering two years, comprises four parallel sections, as follows: (1) administrative section, intended to prepare interpreters and secretaries for the public service; (2) normal section for the training of teachers and candidates for admission to the school of medicine; (3) commercial section; (4) technical section, which prepares for positions in the telegraph and railway service and in public works of various kinds. Students who complete this cycle and pass the final examination receive a diploma, with the mention of their special section. The college has a boarding department, and also a select preparatory division which serves as a practice school for the normal students.

The present Governor-General of Indo-China, M. Klobukowski, is in full sympathy with the reformed system adopted by his predecessor, M. Beau, but proposes to carry it still farther by organizing the secondary schools in two sections, a section of letters comprising in the same program French literature and the oriental classics, and a technical section comprising three divisions: agricultural, industrial, and commercial. At the same time M. Klobukowski is making special provision for the education of native girls.

Of necessity the system of modern education, elaborately planned by the French authorities in Indo-China, has thus far made but little real progress. Official reports for 1909 give the following particulars: Cochin-China (population 2,968,529) had 350 communal and cantonal schools and many private schools. About 40,000 pupils were receiving modern instruction. Schools for girls were conducted in all the principal towns, the most flourishing at Saigon.

In Tonking (population 10,000,000) thirty-eight schools had about 4600 pupils in the Franco-Annamite sections. The schools for girls at Hanoi enrolled 173 pupils, and that at Namdinh, 107. The *Collège du Protectorat* registered 200 boarding and 400 day pupils. The principal teachers in the modern schools of Indo-China are trained in the *École Jules Ferry*, maintained by the *Mission laïque fran-*

*çaise* at its seat in Paris. This society inspired by the enthusiastic purpose of its founder conducts a vigorous propaganda in the interests of French secular education in the Orient. The French schools for Europeans in Indo-China are similar to those of France. In 1909 there were seventeen public schools of this class, with 1087 pupils.

In all the French colonies the support of the public schools is derived from local funds, municipal or communal and provincial, with subsidies from the colonial treasury and from that of France. The French colonial budget for 1909 carried a total of 6,008,139 frs. (\$1,201,628) for public instruction. This sum was distributed as follows: colonies in America, 2,078,022 frs. (\$415,605); in Africa, 2,521,213 frs. (\$504,243); in Australasia and Oceania, 183,149 frs. (\$36,630); in Asia, 1,225,755 frs. (\$245,151).

**FRANCISCANS.** — The name borne by the members of the three great religious orders founded by St. Francis of Assisi (d. 1226), namely the Friars Minor (1209), the Poor Ladies, or Clares (1212), and the Brothers and Sisters of Penance, or Tertiaries (1221). It is the first of these orders that will here be dealt with chiefly, since the educational aspect of the work of the Franciscans is confined very largely to the Friars Minor. In founding this order, however, St. Francis did not intend it to engage primarily in educational work. His aim was to reestablish by its means the principles of the Gospel and to rekindle the spirit of Christian charity. To this end, piety and not science was the one thing needful. So great, indeed, was Francis's enthusiasm for influencing men's lives by example that he did not at first encourage anything like learning among his followers. But, with the rapid growth of the new order and the diffusion of its influence in almost every sphere of life, he was obliged to consider conditions foreign to

his original design. Already in the lifetime of St. Francis his friars began to frequent the universities, and within thirty-five years after his death they had become as conspicuous for intellectual activity as the Dominicans, with whom the Franciscans share the most prominent place in the revival of learning.

**Intellectual Activity.**—The Franciscans soon perceived the need of acquiring a hold upon the centers of education. In 1230 they established a school for their own members in Paris, which soon became so famous that it was incorporated with the university, where the Franciscans subsequently held two chairs of theology. Six years earlier (1224) their school was opened at Oxford, and, after its incorporation with the university, it became a center from which teachers went out into all England, and even abroad. The Franciscans had also from 1225 a school in connection with the University of Cambridge, which continued to choose its regent from among the friars up to the Reformation. Prior to that time there were sixty-seven Franciscan professors at Oxford and seventy-three at Cambridge. Their influence also made itself felt, though to a less degree, at the universities of Bologna, Cologne, Toulouse, Dublin, Alcalá, Salamanca, Prague, Vienna, and Heidelberg, where at different periods the friars filled with distinction the professorial chairs. The great names of Alexander of Hales (d. 1245), St. Bonaventure (d. 1274), Haymo of Faversham (d. 1244), Adam de Mariseo (d. 1258), John Pecham (d. 1292), John de la Rochelle (d. 1245), Richard of Middleton (d. c. 1300), Roger Bacon (d. 1294), Duns Scotus (d. 1308), and William of Ockham (d. 1347) witness to the leading part borne by the Franciscans in the work of the medieval universities. The order has always retained its place in the van of theological and philosophical learning. Over fifty Franciscans assisted as consultants at the Council of Trent (1545), including the great Spanish theologians De Castro (d. 1568) and Vega (d. 1560).

Besides the two great branches of theology and philosophy, the Franciscans applied themselves eagerly to the allied sciences. From the outset they made great progress in Biblical studies. In all one hundred Franciscans wrote commentaries on the Bible as a whole, while about five hundred produced works on particular books of Scripture. St. Anthony of Padua (d. 1231) drew up the first *Biblical Concordance*, and the *Biblical Dictionary* compiled by John Marchesino (d. c. 1300) was in constant use in the Middle Ages. Both these works were surpassed by the *Commentaries* of a third Franciscan, Nicholas of Lyra (d. 1340), the most influential exegete of medievalism, which were often reprinted during the fifteenth and sixteenth centuries and enjoyed a great circulation even among non-Catholics. The first translations of the Bible into Spanish,

Polish, and other European vernaculars were made by members of the order. The Franciscans have not been less fruitful in ascetical and mystical writers, and some of their early devotional works have exercised an immense influence upon the spiritual life of the people. Thus the *Meditationes Vitæ Christi* almost fashioned the crowds in the fourteenth and fifteenth century, as they assuredly gave rise to the miracle plays by which the friars amused and instructed the multitudes, while the *Speculum Christianorum* of Theodore Coelde (d. 1515) attained such popularity that it was reprinted three hundred times. To the Franciscans, moreover, are due two of the greatest Latin hymns, the *Dies Iræ* and the *Stabat Mater*, composed by Thomas of Celano (d. c. 1260) and Jacopone of Todi (d. 1306) respectively, while the *Lauda*, the popular sacred song, especially in southern Italy, had its origin in the vernacular poetry of the order. And the early Franciscan legends, which inspired that classic of Italian literature known as the *Fioretti*, were no less the inspiration of thirteenth-century art in Italy.

The Franciscans did not confine their literary activity to the domain of sacred science only. An English friar, Bartholomæus Anglicus, fl. c. 1231, was the author of *De Proprietatibus Rerum*, in nineteen volumes, an important encyclopedia of the Middle Ages. Fourteen editions of this vast work appeared in Latin before 1500, and, as it was also made accessible to the laity by translations into the vulgar tongues of most European nations, it exercised a great influence on medieval thought. In the same century John Giles of Zamora, the chief collaborator of Alfonso X in that monarch's efforts to foster education in Spain, published an encyclopedia in six volumes of all the historical knowledge then accumulated. The *Doctrinale Puerorum*, a Latin grammar in verse, written about the middle of the thirteenth century by Alexander of Villedieu, likewise holds an important place in the literature of the Middle Ages. It was printed over three hundred times, and up to the fifteenth century was in use in almost all the schools of Europe.

Nor were the Franciscans without great names in the natural sciences. Roger Bacon anticipated in a marvelous manner many modern scientific discoveries, and Berthold Schwartz (d. c. 1384) contributed much to extend the then scanty knowledge of nature by his researches in alchemy. At a later period Luca Paciolo (*q.v.*) was preëminent for his mathematical attainments. He wrote the first book on algebra ever printed, and did much to bring bookkeeping to comparative perfection. Still later Fortunatus of Brescia (d. 1754) was a pioneer in microscopical research, and Marantus Velloso (d. 1811) one of the foremost among South American botanists. The order has also produced architects like

Philip of Campello (fl. c. 1252), the master builder of both Assisian Basilicas; artists like Jacopo da Turreta (fl. c. 1290), who executed the famous Lateran mosaics, and musicians like Julian of Speyer (d. 1250), director of the French royal chapel during two reigns. The Spanish statesman, Cardinal Ximenes (d. 1517), was a Franciscan, and is remembered as a generous patron of learning. He founded and endowed the University of Alcalá, and supervised the publication of the Complutensian Polyglot Bible, the first of the class (1502-1510). In the sixteenth century the Irish Franciscans rendered signal service to letters by their celebrated work, the *Annals of the Four Masters* (1632-1636), chiefly compiled by Michael O'Clery, and by their other historical and literary labors directed by such scholars as Luke Wadding (d. 1657), the annalist of the Order and first rector of the Irish College in Rome. During this century also public gymnasia were opened in several provinces of the order, principally in Germany, Belgium, and the Tyrol.

**Missionary and Educational Activity.**—Notwithstanding their literary and academic pursuits, the Franciscans were first and foremost men of action, not schoolmen or bookmen. Unlike the monks of cloistered orders, they came and went amongst those who had most need of them. From the outset their cloister was wherever there were souls to be saved or hearts to be comforted. They nursed the lepers, helped the laborers in the harvest field and the wounded on the battlefield, cheered the traveler, succored the sick, the sorrowful, and the sinful in the medieval cities. Although they labored for the betterment of all sections of society, yet the Franciscans found their mission mainly among the poor and oppressed. In England they sided with Simon de Montfort in the struggle for liberty, and to their influence may be partly traced the birth of the idea of popular government in different parts of Europe. They were frequently employed as peacemakers between warring peoples and rival factions, and the prolonged efforts of the order to bring about a reunion of the Greek Church with that of Rome are a matter of history. Two Franciscans, Barnabas of Terni (d. c. 1474) and Bernardine of Feltria (d. 1494), were chiefly instrumental in founding the celebrated *monti di pietà*, or charitable loan institutions designed to protect the poor against the usury of the Jews. In other respects also the Franciscans did most meritorious social work, notably by their devotion to the plague-stricken in 1528 and at other periods. The erection of hospitals and the care of orphans was another work of mercy to which they dedicated themselves, and in which Ludovic of Casoria (d. 1885) became most conspicuous in recent times. The modern "Apostle of Temperance," Theobald Matthew (d. 1858), belonged to the Franciscan Order.

The great enthusiasm of the friars and their

zeal for the spiritual and even temporal welfare of their neighbors, as well as their absolute poverty, which appealed to the faith and idealism of the people, added immensely to their popularity and influence as preachers. They usually preached in the public squares or from the village crosses, and their sermons were cast, not in the abstruse language of the schools, but in the homely phrase of everyday life, and thus appealed directly to the people. The missionary labors of the order were not confined to quickening the piety of European nations; but were to a large extent accompanied by educational and philanthropic work. And these still remain as features of the order.

Thus in Palestine, where the Franciscans have been active missionaries since 1219, they conduct, in addition to hospitals, dispensaries, and hospices, fifty-nine elementary schools, thirty-eight for boys and twenty-one for girls, besides ten trade schools, and one commercial and classical boarding college at Aleppo, which is renowned throughout the Orient. At Jerusalem there is maintained a printing establishment, from which many educational and religious works in different languages are issued annually.

In China the Franciscans have labored since the thirteenth century. Before its close John of Monte Corvino had built a church "with dome and bells" at Cambalu (Pekin), and was able to report that he had taught Latin and Greek to 150 boys and had converted 600 people, for whom he translated the New Testament and the Psalter into Chinese. At present there are 220 Franciscans in sixteen Chinese missions, including eleven bishops, all of whom belong to the Order. They serve 3049 churches and chapels, and conduct twelve seminaries with 582 seminarians, fifteen colleges with 589 students, 780 schools with 21,965 pupils, besides maintaining orphanages and hospitals. The Franciscan missions in Japan, which were destroyed in 1597, were reopened in 1907. In India the Franciscans had numerous colleges and schools long before the arrival of the Jesuits, who first came there under the Franciscan Archbishop of Goa, John Albuquerque (1537-1553). Four of the principal dioceses in India are now entirely served by the Capuchin Franciscan Friars, and native Tertiary Brothers conduct schools and asylums. Franciscan activity in the Philippines dates from 1577. There, as elsewhere, they established schools and instructed the natives in manual labor—the planting of coffee and cocoa, breeding of silkworms, weaving, building bridges, canals, etc. Of those within the Franciscan pueblos 85 per cent could read and write and knew the elements of arithmetic. Several of the Philippine missionaries wrote valuable works in the vernaculars of the natives. Thus in addition to several catechisms, dictionaries, and grammars, which were often recited, John

of Plasencia (d. 1580) composed a history of the Philippines, dealing particularly with the rites, usages, and customs of the natives, which long remained the standard authority on the subject.

**America.** — As is well known, the Franciscans were the first missionaries in America, seven members of the Order having accompanied Columbus on his second voyage; and at Hayti a Franciscan opened the first Christian church in the New World (1493). The first schools in America were opened by the Franciscans in connection with their churches at Nueva Isabella and La Vega, and there the Indian boys were taught reading, writing, and singing. The Franciscans were also the first missionaries on the mainland or continent of America (1512). Not to speak of the labors of the order in Brazil, where since 1891 five new missions have been established among the more savage natives, Peru, Chili, Argentina, Paraguay, Bolivia, and Venezuela, it was Franciscans who planted Christianity in Mexico (1523), whence they went forth to evangelize Florida (1528), New Mexico (1539), Texas (1685), and California (1769). As early as 1531 the college founded by Peter of Ghent in the city of Mexico was attended by more than 600 Aztec youths, and every Franciscan convent in the diocese had a school attached to it. In these schools as many as 600 or 800 pupils received instruction, food, and clothing from the friars with whom they made their home. These institutions were the first free boarding and trade schools on the American continent. The instruction given in these schools was of a twofold character. Up to the age of nine the children were taught reading, writing, catechism, singing, and instrumental music; from nine years on, the work of the pupils was almost wholly industrial, the common arts and trades of the civilized world forming the curriculum. It was the Franciscan John Zumarraga, first Bishop of Mexico, who set up the earliest printing press in that country (1537-1538) and published the first book there, a compendium of Christian doctrine, in Mexican and Spanish (1539). Out of 118 books printed in Mexico up to 1600, the Franciscans brought out 41. Among these the *Vocabulario* by Alfonso di Molina (1555), containing 510 pages in folio, is still regarded as a standard. The earliest schools within the present limits of the United States were founded in Florida and New Mexico by the Franciscans, who began the work of evangelization and education in the chief towns of the tribes, a school being erected alongside of each church. In Florida the educational work of the Franciscans on a systematic scale dates from about 1594, and in 1606 a flourishing classical school and preparatory seminary for the children of Spanish settlers existed in St. Augustine under their direction. They also conducted a free school

at St. Augustine from 1785 until the union of Florida to the United States in 1819. It is worthy of note that Francis Pareja, one of the foremost of the Franciscan missionaries in Florida, published (1612-1617) a grammar, several catechisms, and a number of other works in the Tunuquan language, these being the first books printed in any of our North American Indian tongues. The system of schools set up by the Order in New Mexico comprised in 1836 the entire school population of the tribes or the natives converted to the Faith. The educational work of the Franciscans in Texas began in 1689, San Antonio being the chief center of their missionary activities. In Lower California the school system established by the Order dates from 1769, when Juniper Serra (d. 1784) founded at San Diego the first of the famous Franciscan missions, which were in fact immense boarding schools.

Nothing perhaps is more striking in connection with the remarkable success attained by the Franciscans in converting and civilizing the natives in the region above mentioned than the prominence given to education in their missionary work. There can be little doubt that this was largely due to the wise regulations framed by Cardinal Ximenes (1516) with respect to the natives of the New World, which were the guiding principles of the members of his Order, in providing that each settlement was to have its school as well as its church.

The Franciscans, as Baneroft notes, were the first missionaries ever north of the Potomac, as they had been the first south of it. They were the pioneers of the Gospel in Canada and what are now the Northern and North-western states of the Union. As early as 1575 Andrew Thevet published an account of his travels in Maine, and another Franciscan, Gabriel Sagard, was the first to publish a history of Canada (1619). In 1615 the Franciscans inaugurated the missions in the interior of Canada in which the Jesuits labored later on, and they opened many schools for the Indian boys. The first dictionaries in the Iroquois, Algonquin, and Huron languages were compiled by Joseph La Caron (d. 1632) and completed from the notes of Nicholas Viel (d. 1625), both Franciscans. The Franciscans still bear a great share in the missionary work among the American Indians, especially in Arizona, New Mexico, California, Wisconsin, and Michigan, where they conduct a number of Indian boarding, day, and trade schools. At Harbor Springs they publish from their own press a monthly periodical in the Chippewa language. Besides catechisms and grammars in the language of the Chippewas and Menominees, they recently (1910) issued in New Mexico a *Navaho-English Catechism* and an *Ethnologic Dictionary of the Navaho language*.

From the outset the missionaries of the

Order have also furnished very valuable descriptions of foreign countries and peoples. In this class of writings the *Relations* of John of Pian di Carpino and of William of Rubruck, who penetrated through Tartary and Armenia in the thirteenth century, have an enduring value. In many respects the monumental work of Quaresmio (1625) on the topography of Palestine has not yet been superseded. The writings of Hennepin (d. 1706) contain the first description of Niagara Falls and the fullest published account of De la Salle's first expedition, while the *Chronicle* of Epinoso remains a standard work on the missions of Texas.

The *Scriptores Ordinis Minorum* of Wadding-Sbaralea contains over 4000 historical and critical notices of writers belonging to the Franciscan Order, including the names of chroniclers like Salimbene (d. c. 1288), historians like Crabbe (d. 1554) and Pagi (d. 1699), and orientalists like Galatino (d. 1540) and Smits (d. 1770). But the great majority of the Franciscan writings are closely connected with the apostolic labors of the Order. For it must be borne in mind that the ideal and mission of the Franciscans is primarily a spiritual one. With this aspect of the work of the Order we are not directly concerned here. It will suffice, therefore, to note that it has produced a great number of saints, of whom 241 have been formally canonized or beatified. Five popes have been chosen from among the Franciscans, including the great Sixtus V (d. 1590). The Order has also given to the Catholic Church over 100 cardinals and at least 3000 patriarchs, archbishops, and bishops. At present there are two Franciscan cardinals and forty-two archbishops and bishops belonging to the Order. Numerically the Franciscans form the largest religious Order in the Catholic Church. The First Order of St. Francis actually numbers about 29,000 members, of whom 16,900 belong to the Friars Minor, 10,000 to the Capuchins, and 1500 to the Conventuals, these being the three great branches into which it is divided. These friars are distributed over the five continents, and possess convents and hospices in almost every part of the world. In the United States the Friars Minor alone have four Provinces, comprising 107 houses and 1010 members, of whom 519 are priests; they conduct one ecclesiastical seminary, two classical and commercial colleges, and have under their direction 157 parish schools, attended by some 32,000 children, besides five preparatory colleges and twelve houses of study for members of the order exclusively. Those destined to teach in these study houses are required to pursue a special course of higher studies in Rome at the International College of the Order, and to qualify for the doctorate. The official printing press of the Friars Minor is at the College of Quaracchi, near Florence, whence are issued *éditiones principes* of the writings of

the great Franciscan scholars and other works of varying importance. Here too are published the monthly *Acta Ordinis Minorum* and the learned quarterly *Archivum Franciscanum Historicum*. In spite of the fact that the general usefulness of the friars has been hindered at different periods in their history by more or less mystical disputes among themselves as to the observance of their rule, which, owing to its extreme simplicity, lent itself to a great variety of interpretations, the Order has in all its branches always maintained its great popularity.

As regards the Second Order of Franciscans, known as the Poor Clares, it now numbers about 11,330 nuns, divided among 599 monasteries, of which seven are in the United States. These nuns are strictly cloistered, as the Order was founded at an epoch (1212) when women might not have a share in active apostolic work. At different times and places, however, the Poor Clares have undertaken the instruction of young girls, notably in Mexico about 1530, and it is worthy of mention that the first Sisters' School in the English-speaking states was opened by members of this order in 1801 at Georgetown, D.C.

Not the least useful part of the present educational work of the Franciscan Order has been done by the members of its Third Order Regular, Brothers and Sisters living in community, but observing a more mitigated rule than that of the First or Second Order. Of these Regular Tertiaries, as they are called, there now exist sixteen separate congregations of men, with ninety houses and nearly 1200 members; of women there are 309 different congregations, with 3217 houses and 46,110 members. The largest number of these Tertiary Franciscans are engaged in teaching in colleges, academies, or parish schools in the United States or in the foreign missions of the Order. In addition to this Third Order Regular, and quite independent of it, is the Third Order Secular, established by St. Francis in 1221, and embracing devout persons of both sexes living in the world under the spiritual direction of the Franciscans. At present 7140 congregations of such Secular Tertiaries exist under the direction of the Friars Minor alone, numbering in all 1,489,611 members. Historically the most interesting point in relation to this Third Franciscan Order is the fact that its organization went far to give the deathblow to the feudal system in Italy, and that as time went on it reckoned among its members many remarkable men, including Raymond Lully, Columbus, Giotto, Galileo, Tasso, Petrarch, Murillo, and Palestrina. P. R.

**FRANCKE, AUGUST HERMANN** (1663-1727). — One of the most prominent German educators and philanthropists, the chief pedagogical representative of Pietism (*q.v.*), born in Lübeck. Francke received his early education from private tutors at home. From childhood up he showed an inclination to enter the ministry, and spent much time in religious exercises, regarding the ordinary plays of children as a sinful occupation. In 1676 the precocious boy was sent to the highest class of the Gotha gymnasium, where he came under the influence of the educational reformer Andreas Reyher (*q.v.*), who was attempting to introduce the methods of Ratke and Comenius into the schools of the duchy. In 1679 he entered the neighboring university of Erfurt, which, however, he left in the same year, having through the influence of his mother's family received a lucrative scholarship at the University of Kiel. In Kiel he remained three years, studying chiefly theology, but also attending lectures on philosophy, philology, and history. In order to perfect himself in the study of the Hebrew language, he spent some time with the distinguished orientalist Edzardi in Hamburg. In 1685, having received the master's degree from the University of Leipzig, he began to lecture there, and in the following year formed a club of young university teachers and of students for the purpose of studying the Bible in the original. This club, called the *Collegium Philobiblicum*, attracted great attention, and gained for Francke the friendship of Spener (*q.v.*), who then occupied the position of Court preacher in Dresden. After an absence of about two years from the university, during which time his religious life was deeply stirred, he returned to Leipzig, where his lectures on New Testament exegesis and his religious zeal brought him great popularity,

but, at the same time, drew upon him the jealousy and hatred of some of the orthodox professors. In 1690 he was called to a pastorate in the city of Erfurt; but through the enmity of the conservative part of the clergy he was soon deposed from his office, and even driven from the city. At this time, however (1691), he received a call as professor of oriental languages to the newly founded university of Halle. This call represents a turning point in Francke's life. With this professorship was connected the charge of the parish of Glaucha, a poor suburb of Halle, in which Francke soon developed a most zealous evangelistic philanthropic activity. In 1695, having found the sum of seven florins in his collection box, he determined to use it for the foundation of a school for the poor. From this small beginning there soon grew up a large system of educational and philanthropic institutions, which has existed to the present day, and now, under the name of Francke Foundations (*Franckesche Stiftung*), forms almost a suburb of the city of Halle. To the charity school was added an elementary school for the children of the citizens of Halle, then an orphan asylum, a boarding school for boys of well-to-do families, the so-called Pädagogium, and, in 1696, a training school for teachers, the *Seminarium Præceptorum*. Besides these, he established, in 1697, a Latin school, to which the sons of citizens and the more talented boys of the orphan asylum were admitted, and in 1698 a boarding school for girls, *Gymnasium*, which, however, had to be discontinued in 1705. To house these various institutions, he gradually acquired a large plot of land, on which a number of buildings were erected. The necessary means were obtained partly through gifts, which came in from all parts of Germany, and partly through several commercial and industrial enterprises, a paper mill, a bookstore, a printing press, from which was issued the famous *Canstein Bible*, a pharmacy, and others, the income of which soon became considerable. In 1708 King Frederick I of Prussia visited the institution and conferred upon it valuable privileges.

Francke was a man of remarkable energy and wonderful organizing ability. His fundamental characteristic was a deep religious conviction, which, however, was not a matter of feeling, but of will. Francke's pedagogical writings fall into two classes, but the spirit of pietism underlies both. In the one class he devoted himself to explaining the importance and method of religious teaching, the most important work of this type being the *Kurzer und einfältiger Unterricht wie die Kinder zur wahren Gottseligkeit und christlichen Klugheit anzuführen sind* (*Short and Simple Instruction for leading Children to True Piety and Christian Wisdom*), first published in 1702, but probably written earlier, as the basis of his pedagogical lectures at Leipzig in 1698 on *De Informatione*

*Actatis Puerilis et Pubescentis (On the teaching of Children and Adolescents)*. In the second class are the ordinances for the management of his schools and for the direction of inspectors and teachers, e.g. *Ordnung und Lehrart der Waisenhaus-Schulen (Organization and Teaching Method in the Orphan Schools)*, and *Instruction des Inspectoris Scholarum*.

The institutions under Francke's management had the greatest influence on education in several directions. Orphan asylums sprang up throughout Europe, modeled on those at Halle; thus they were soon founded at Königsberg, Züllichau, Langendorf, Stettin, Potsdam, etc. With these institutions were frequently linked up training schools for teachers, which in their turn had considerable bearing generally on the training of teachers in Germany. A new spirit was introduced into the classroom, and was of great importance in educational development. (See PIETISM.) A large number of educational leaders went out from Francke's institutions, the most notable being Hecker and Count von Zinzendorf, who founded the institution of the Bohemian or Moravian Brethren. The secondary schools of Francke became centers for the spread of real studies. To the study of Greek, Latin, and Hebrew there were added French, rhetoric, history, geography, mathematics, arithmetic, botany, mineralogy, astronomy, and anatomy, and visits were made to local workshops and factories. But while Francke included these additional subjects for purposes of recreation, his pupil, Hecker, made them the center of studies in the *Realschule* in Berlin. (See REALISM.) The foundation continued successfully under Francke's successors until 1770, when the falling off of contributions, the rise in prices, and the disturbed state of central Germany threatened the institution with extinction. From this it was saved by A. H. Niemeyer, who became director in 1785 and secured the interest and good will of Frederick William III, and insured the permanence of the institution.

The *Franckesche Stiftungen* now consist of the following educational institutions: Latin Central School; *Oberrealschule* (founded in 1835 as a *Realschule*); High School for Girls (1835), with which is combined a Normal School for Female Teachers (1879); a boarding house for about 250 pupils in the secondary schools; a preparatory school; a *Bürgerschule* for boys and one for girls; an orphanage for boys (121) and one for girls (18); a *Seminar* for the training of secondary school teachers (1889). The institution receives state support, and is in a position to give a large number of scholarships, including, in many cases, board and lodging. There are about 3000 children and 100 teachers connected with the foundations. Through the present director, Dr. Wilhelm Fries, who is also professor of pedagogy in the University of Halle, a connection is maintained between the University and the schools.

**FRANCKESCHE STIFTUNGEN.**— See FRANCKE, AUGUST HERMANN.

**FRANKFORT-a.-M., UNIVERSITY OF.**—

A proposal to found a University in Frankfort-a.-M., projected for several years, culminated in April, 1911, in definite plans for such an institution to be opened in 1914 with three faculties, law, philosophy, and medicine. Interest centers in this institution as the first seat of higher learning for many centuries in Germany to be founded through private endowments and municipal grants. Although it owes its origin to private initiative, it will be under Prussian state control in the same way as other universities. Frankfort has for some time enjoyed facilities for higher studies, and it is proposed to make these the nucleus for the new foundation. The most important of the institutions has been the Academy of Social and Commercial Sciences, which was established in 1901 through the combined efforts of the town, the Institute for the Common Weal, the Chamber of Commerce, and the Polytechnic society and three other endowed bodies. It is under the authority of the Prussian ministers of Education, and of Commerce and Industry. In addition to providing commercial training, the Institute also offers courses in various phases of administration, in social and political sciences for civil servants, judges, lawyers, and others. Teachers who are preparing to teach in commercial, industrial, and continuation schools, and those who are preparing to qualify as teachers of modern languages in secondary schools, find adequate courses here which are recognized by the authorities. Lectures and conferences are held also on Germanic languages and literatures, psychology, pedagogy, history, art, mathematics, geography, physics, and chemistry. Students who have completed studies equivalent to the requirements for one year military service are admitted. In 1909-1910 there were enrolled 1693 students, of whom 604 were women and 47 were foreigners. Further, the city is well equipped with hospitals and clinics; since 1899 it has been the seat of the *Königliches Institut für Experimentelle Therapie*; of the *Dr. Senckenbergische Stiftung* (f. 1763), which maintains a hospital, medical library and institute, and a botanical garden, and provides courses of lectures in the winter on botany, anatomy, and pathology; of the *Freies Deutsches Hochstift*, a foundation for the promotion of higher learning (f. 1859); and of several other institutions with similar aims in other branches

of study. The greater part of the money needed to establish the new university and to provide an annual income for its maintenance has now been secured. The Frankfort University represents not only popular interest and local initiative in higher education, but also the tendency of university life to drift away from the older foundations in small towns to the larger cities.

**FRANKFORT-a.-ODER, UNIVERSITY OF.** — A *Studium Generale* was established here in 1506 by Joachim I of Brandenburg, himself a scholar, with four faculties of theology, law, medicine, and arts. Although the founder intended the institution to be a seat of the humanistic studies, the earliest professors were mere pedants, and the progress was also hindered by the distant location of the town and by plague. In 1537, however, Joachim II entered into negotiations with Melancthon (*q.v.*) for the reorganization of the university, and when, two years later, he became a Protestant, he made over certain monastic property to the university. Strongly entrenched as the first Hohenzollern university, the institution continued until 1811, when it was necessarily overshadowed by the new foundation at Berlin. As a result, the university was combined with the Jesuit university at Breslau as the Royal University of Breslau (*q.v.*).

**FRANKFORT PLAN.** — See GERMANY, EDUCATION IN.

**FRANKLIN AND MARSHALL COLLEGE, LANCASTER, PA.** — An institution formed by the union of Franklin College (1787), Lancaster, and Marshall College (1835), Mercersburg, both institutions which were originally founded for the education of the German population of Pennsylvania. The two were united in 1853, and located at Lancaster. The college is under the general control of the Reformed Church in the United States. The campus of fifty-four acres contains ten buildings. Academic and collegiate departments are maintained. Students are admitted by certificate from approved high schools, or by examination the requirements for which are about fifteen units. Advanced degrees are also given. The faculty consists of sixteen members.

**FRANKLIN, BENJAMIN** (1706-1790). — The American author, scientist, and statesman; influenced the educational theory and practice of his country and his time in many ways, — through his practical improvements in the art of printing and his influence as a newspaper publisher and editor, and as the author of countless public letters, essays, and pamphlets, and of his *Poor Richard's Almanac* and his *Autobiography*; through his founding the first American circulating library (1731), the academy that developed into the University of Pennsylvania (*q.v.*) (1743), and the American Philosophical Society (*q.v.*) (1769); through his manifold and multiform civic services; through his scientific discoveries, like that of the identity of electricity and lightning, and his practical inventions, such as the stove that bears his name; through his inestimable patriotic and diplomatic services as postmaster-general, member of the Continental, Constitutional, and many other congresses, as Commissioner and Minister in England and France during and after the American Revolution, and, repeatedly, as president (or governor) of the State of Pennsylvania; and, finally, through his humanitarian leadership in such organizations as the Pennsylvania Society for the Abolition of Slavery. It is, therefore, scarcely surprising that no one has as yet undertaken a definitive tracing of Franklin's educational influence through the masses of contemporary literature, or even through the 20,000 items of his manuscript that are available, in addition to the 1806 items printed in the latest edition of his Works (excellently edited, with a life, by Professor Albert Henry Smyth; 10 vols., 1905-1907).

The educational influences of the *Poor Richard's Almanac* and of the *Autobiography* are, however, obvious. The proverbs invented, adapted, or quoted in the twenty-five annual editions of the former (1732-1757), and condensed in *The Way to Wealth* in the latter year, circulated everywhere in their original form and were reprinted on broadsides at home, and were translated throughout Europe, as "the most famous piece of literature the Colonies produced." Many of their teachings concerning industry, frugality, and resolution, enforced by their humor and preserved by their compact, sententious form, are still current in phrases like "God helps them that help themselves," "Honesty is the best policy," and "Diligence is the mother of good luck."

Franklin's incomplete *Autobiography* (written in 1771, 1784, 1788, and 1789), has been called the most widely read American book, and the most popular book of its kind in any language. More than one hundred editions testify to its extraordinary influence. It completely embodies the ideal of an industry that defined leisure as "time for doing something useful," a frugality that was indifferent to food and fur-

nishings, and a worldly wisdom that knew how to prize every small advantage and took care not only to be industrious and frugal, but also to appear so. It illustrates the ways in which manual dexterity and ingenuity, together with social curiosity and attractiveness, may lead to employment and advancement; and how deference, promptness, and reliability may establish both. It pictures the self-education of a voracious reader, — French, Spanish, and Italian making an easy way to Latin; and study of the *Spectator's* arrangement and expression and of Bunyan's combination of narrative and dialogue leading to a flexible and lively style. The effect of the author's newspapers, pamphlets, and state papers is cited as proof of the usefulness of his method and of the importance of the ability to write easily and well. The detailed accounts of the founding of the library, the academy, and the philosophical society; of the regulation of the city watch, the development of a fire company, the inauguration of street paving, and the improvement of street lighting; and the accounts of numerous larger civic and patriotic services all helped to formulate and promulgate a noble tradition of social and patriotic usefulness. The indication of how one might use public office to help one's self but not to hurt others, the refusal to profit from patents or public contracts, the appreciation of the good that might exist in hypocritical, indifferent, or indecisive public officers, the justification of small deceptions for the public good, the ability to be friendly with political enemies, and the determination never to ask, refuse, or resign an office, — the frank record of all of this is like the beginning of the checkered map of political life in a democracy. The book's reprehension of unfairness, bad faith, unkindness, and open irreligion or immorality helped the upbuilding and maintenance of the social conscience. The usefulness of morality to prosperity and happiness, and the value of the thirteen selected virtues of industry, frugality, cleanliness, order, chastity, temperance, moderation, sincerity, justice, humility, silence, resolution, and tranquillity, — these constituted the foundation of a very practical, if not a very lofty, system of morals. The theology of the autobiography is very simple, — churches being mostly given over to questionable doctrine and sectarian zeal, the worship most acceptable to the Creator and Judge of all the world is service to his creatures. This creed, so forcibly preached and practiced by Franklin throughout his life, found wide, although not always open, acceptance.

Of Franklin's writing specifically concerning education, four occasional pieces are especially important. A *Proposal for promoting useful Knowledge among the British Plantations in America* (1743) recognizes that, while the first drudgery of settling had given place to circumstances that allowed the cultivation of the arts

and the improvement of knowledge, men whose observations and speculations might produce discoveries of advantage were yet widely separated; and therefore suggests that their mutual correspondence be furthered by an organization, called the American Philosophical Society, with headquarters and regular meetings in Philadelphia. This society was finally inaugurated in 1769; Franklin continued to be its president until his death; and many eminent men have cooperated in carrying out the plans of the founder, with notable scientific results, down to the present day.

Concerning the academy that has been mentioned, Franklin wrote three conspicuous and various minor papers, and many letters. *Proposals relating to the Education of Youth in Pennsylvania* (1749) first suggested the establishment and outlined the curriculum of the academy. "It would be well if they," it says, concerning the pupils, "could be taught everything that is useful, and everything that is ornamental. But art is long, and their time is short. It is, therefore, proposed, that they learn those things that are likely to be most useful and most ornamental, regard being had to the several professions for which they are intended." The essentials are then indicated, as: clear and rapid penmanship; something of drawing and perspective; arithmetic, accounts, and some geometry and astronomy; English grammar, pronunciation, and composition, taught through oratory and debate and the writing of letters, abstracts, and reports; some geography; biography for its moral lessons; much history, for its illumination of politics, religion, and citizenship, and its incidental incitement to the study of ancient and modern foreign languages; natural history, with observations, excursions, and practical exercises; and, finally, the history of commerce, invention, and manufacture, with an introduction to mechanics. "With the whole should be constantly inculcated and cultivated that benignity of mind, which shows itself in searching for and seizing every opportunity to serve and oblige, — the great aim and end of all learning." *An Idea of the English School* for the academy (1750), gives many specific and often ingenious suggestions for the teaching of English grammar, spelling, pronunciation, reading, and composition, and the correlation of these with other studies, all arranged for six successive classes. *Observations Relative to the Intentions of the Original Founders of the Academy in Philadelphia* (1789) regretfully records, in Franklin's last year, how his yielding to other supporters of the academy of his strong prepossession against including foreign languages in the curriculum was followed by the trustees favoring the Latin and neglecting the English school, until the latter declined and was discontinued. This whole procedure was characterized by Franklin as not only shamefully disregardful of the original constitution

of the academy, but also as foolishly prejudiced in favor of ancient customs that were quite unsuited to so new a country.

Finally, there are among Franklin's published writings numerous brief pieces, such as *A Scheme for a New Alphabet and a Reformed Mode of Spelling* (1768) and *A Petition of the Left Hand* (undated), and his many published letters contain much of educational interest. The 20,000 manuscript items of his writing and the countless contemporary sources bearing upon his life and work still await educational exploration. (For portrait, see opp. p. 255.)

**FRANKLIN COLLEGE, FRANKLIN, IND.**

— A nonsectarian, coeducational institution, which owes its establishment to the Baptist General Association of Indiana (now the Indiana Baptist Convention), organized in April, 1833. In 1844 a college charter was received and a regular collegiate scheme of studies was adopted. In 1847 the first A. B. was conferred. The increase of the student body was interrupted by the enlistment in the Union army of practically all the undergraduates, and in June, 1864, the college closed its doors. In 1868 it was reopened. In 1872 a stock company was formed which purchased the plant. The articles of incorporation prescribed that the president and a majority of the trustees should be Baptists. Waivers having been secured from the original stockholders or their heirs, on Oct. 21, 1907, a self-perpetuating corporation of twenty-four members was created, one third of whom should retire each year. No denominational restriction was imposed. Franklin College was accepted by the Carnegie Foundation for the Advancement of Teaching (*q.v.*) in 1908. Admission is by examination or certificate from approved high school; students from Indiana commissioned schools (*q.v.*) are admitted without examination. The degree of A. M. is given for one year's graduate study in residence. Buildings and equipment are valued at \$209,250, the grounds at \$35,000. The productive endowment is \$246,000, yielding an annual income (1911) of \$14,961.04. Fees and tuitions from students amount to \$11,200. The average salary of a professor is \$1200. There are thirteen members of the instructing staff. The students number 275. C. E.

**FRANKLIN COLLEGE, NEW ATHENS, OHIO.**— A coeducational institution founded in 1818, offering three full four-year courses in classical, scientific, and philosophical branches, which lead to their appropriate degrees.

Departments in music and elocution are also maintained. The preparatory department gives about three years of high school work. The faculty consists of fourteen members.

**FRANKLIN UNION, BOSTON, MASS.**

— An institution which owes its establishment to a bequest of Benjamin Franklin (*q.v.*); part of the money at the end of a hundred years was to be expended in "public works which may be judged of most general utility to the inhabitants." The result of the last provision was the establishment of an industrial school built and equipped out of the Franklin fund and maintained from the income of a gift of Mr. Andrew Carnegie. Highly specialized industrial courses are offered in the evening to young men over sixteen under the charge of instructors selected from the leading manufacturing industries. The work of instruction is supplementary to the daily work of the student, and no attempt is made to teach the shop work best learned in the routine of daily employment. Several two-year courses, leading to a certificate, are provided, in addition to shorter courses.

**FRATERNITIES AND SORORITIES IN AMERICAN COLLEGES.**— **Origin and Structure.**—

The permanent, wholesome, and generally democratic character of American college fraternities, their childish secrecy and light-hearted but eager rivalry, and the seriousness with which they are regarded by undergraduates and by most of their alumni make them unique among undergraduate societies of the world. Their history is a study in Americanism. Its most significant feature is the fact that these clubs have developed, practically without the control or direction of the colleges, from two or three irresponsible groups of boys into a system firmly entrenched in American college life, so widespread that few of the hundreds of American colleges are without "chapters" (as the branches of a fraternity are called); and so responsible that the real estate held by the fraternities aggregates in value well into the millions. The undergraduate and graduate membership of the fraternities includes more than 200,000 men, and, in the sororities, about 25,000 women.

The college fraternity usually traces its growth from a single society called the "mother chapter." This chapter in the early years of the society's existence granted "charters," or licenses to establish chapters in other colleges, to groups of young men whom the original members organized, or who were, for one reason or another, interested in the original society. The prerogative of chartering chapters the "mother chapter," in many fraternities, held for the first fifteen or twenty years of the society's existence, — sometimes even longer. It was gradually replaced, however, by the organization which has come to be common.

With permission of *The Sorority Handbook*.  
 BADGES OF AMERICAN COLLEGE SORORITIES.

BADGES OF AMERICAN COLLEGE FRATERNITIES.

The fraternity numbers usually from a dozen to fifty chapters, each chapter enrolling about twenty-five members, — a larger membership is regarded as perilous to the close intimacy which is the purpose of the fraternity. These chapters annually elect delegates to a "national convention," held with a chapter or "alumni club" as the host. The convention, besides supplying enthusiasm and social contact between the chapters, transacts such business as determining the general policy and admitting new chapters. During the period when most of the fraternities were rapidly expanding, it was common for a fraternity to reach out into an institution and deliberately "plant" a chapter there. To-day, however, petitioning bodies are organized and assail the conventions, — often unsuccessfully, and not infrequently for many years before admission. The stronger fraternities are now slow to admit new chapters, and both the college and the personnel of the petitioning body are closely scrutinized. Hence, there is evident a steady and insistent attempt on the part of most fraternities to maintain a high character of membership. During the year between conventions, the government of the typical fraternity is intrusted to a "council," — the "executive council" or "grand lodge" — composed of about a dozen graduate and undergraduate members, — in whose hands all administrative business is left. The kind of man who devotes a large part of his time to such work is, among the graduates, pretty much the recognizable type that is characteristically interested in lodges, clubs, and organization in general. But it is not unusual to find men of even national prominence serving upon these bodies; and, indeed, the hold of the better fraternities upon their alumni members, the strong affection kindled by these intimate societies, is a striking feature of the system. The usual organization of the fraternity has its exceptions in the "local" societies, confined to a single college, — often, as at Princeton and Yale, clubs of antiquity and prestige, — and in the curious system congenital apparently to life at Harvard University, where the clubs form a species of pyramid, the larger societies feeding the smaller and more exclusive clubs in the later years of the course. Aside from Harvard, Princeton, and Yale, the American college is usually a "fraternity college"; that is, its social clubs are chapters of national fraternities and draw their membership from all four years of undergraduate life.

**Historical Development.** — The oldest of the fraternities was organized Dec. 5, 1776, at Williamsburg, Va., as a social and "philosophical" society in William and Mary College. Quite accidentally, the five founders — John Heath was president — selected as a name the three initial letters of a Greek motto, Phi Beta Kappa. The early meetings probably resembled those of modern fraternities, and all the essentials of the present organization were

adopted, including grip and ritual. Local chapters were soon established, one, for instance, at Richmond, Va., which admitted noncollegians. In November, 1780, a chapter was established at Yale; in 1781 the parent chapter ceased to exist, because of the troubled times. In September, 1781, the Harvard chapter was established. Chapters followed at Dartmouth and Union. The society was decreasingly active until 1825, by which time it had become wholly perfunctory. In 1831 it was forced by the president of Harvard to reveal its secrets. It gradually assumed its present character of a purely honorary scholarship society, electing members of the other fraternities and women upon equal terms with men. As such a society it plays to-day an important part in the colleges.

With the exception of Chi Phi, a Princeton society existent in 1824 (as was shown thirty years later by the discovery of its constitution), there was apparently no further attempt to found a Greek letter society until 1826, when Kappa Alpha (7),<sup>1</sup> the first college fraternity of the type existent to-day, was founded at Union College. The period in American social life was one of upheaval. Revolutionary ideas from France were met by the conservatism of a still provincial country. Europe, stirred by revolution and fertile in secret societies, had its influence. Just previous to 1826 Masonry was in an unusually thriving condition. The college boy, quick to mimic the larger world, was more than usually interested in "clubs" — always dear to young manhood. The colleges, too, were centers of storms of a kind they do not now know; young Jacobins still dared expulsion with radical speeches, and there was unusual eagerness to defy the powers in control. On the other hand, intense religious enthusiasm could still sweep over a college, and there existed an aggressive missionary spirit. In 1826 the kidnapping and alleged murder of William Morgan in New York for revealing Masonic secrets led to the formation of the important Anti-Masonic Party, which was the first to hold a political convention. This movement, too, had its effect upon the responsive undergraduates; ferment and organization were in the air, and once begun, the forming of college fraternities was inevitably and even feverishly rapid.

As was natural, most of the first fraternities owed their establishment usually to a desire to form a "clique" within some organization, often in one of the large debating societies in which centered the active college politics of the day. Kappa Alpha was founded in November, 1826, upon the disruption of a college military company because of the inability of its members to agree upon a successor to a popular captain. Five members of the class of 1825, four of them members of Phi Beta Kappa, showed, however, that they were more than

<sup>1</sup> The figures in brackets denote the number of active chapters.

undergraduates organizing a clique. They perfected a form which has been followed by all college secret societies. In its later history this earliest fraternity has remained conservative in the extreme. The average chapter roll of an intercollegiate society includes about twenty colleges; but Kappa Alpha for years numbered only four, and to-day has seven. The fraternity has also been consistently dignified in administration and careful in the choice of its membership. Its badge, like that of Phi Beta Kappa, is an old-fashioned flat watch-key hung as a charm. The other societies use pins worn upon the waistcoat.

At Union College, — often called the "Mother of Fraternities," — originated on Mar. 4, 1827, Sigma Phi (9), a rival modeled after Kappa Alpha, and in the same year Delta Phi (12), the last of the so-called "Union triad." Like Kappa Alpha, these two fraternities have remained conservatively small. They constituted the fraternity system in American colleges until 1832, when Samuel Eells, senior of Hamilton College, with four fellow undergraduates, founded Alpha Delta Phi (24). He died after a short but brilliant career as law partner of Chief Justice Choate; but the fraternity he established may be grouped with two others as occupying a position of unquestioned historic importance in American colleges. These two fraternities are Psi Upsilon (23), founded at Union in 1833, and Delta Kappa Epsilon (42), founded in 1844 as a rival to Psi Upsilon at Yale. The chapters of Psi Upsilon have in most instances had histories of steady prosperity, not a common condition; because of the intense competition due to the overcrowding of many colleges with fraternities, chapters are liable to vicissitudes. Delta Kappa Epsilon is the largest of the fraternities, having a membership of more than 17,000. The three fraternities, which have been called the "historic triad," have been less conservative than the smaller members of the early "Union triad." All three have become national in the distribution of their chapters, though Psi Upsilon waited until 1865 before reaching out as far west as the University of Michigan.

Naturally the fraternities did not exist long without encountering opposition. This came not only from college authorities, dismayed at occasional outbursts of youthful mischief and fearful of the creation of organizations beyond the reach of easy control, but also from a large element among the undergraduates, which included two classes of men: the haters of the fraternity from "political" reasons, — members, for instance, of cliques not so permanent or attractive, — and the sterner moralists and unyielding idealists of college life. Often older and more serious, as well as poorer than their fellows, these included many of the honor men, and probably not a few who in the emphatic college slang of to-day would be spurned as "grinds." Especially, too, in the New England

colleges the opposition to the fraternities was animated by a spirit much like that narrow but zealous one which in the larger world was opposing Masonry and advocating the establishment of a "Christian" party. When Kappa Alpha entered Williams College in 1833, it found opposition ready. By 1834 the "Social" or "Equitable" Fraternity was founded by thirty-three men, eleven from each of the three upper classes. Then came bitter warfare. By 1847 the Williams Society had united with other "anti-secret" organizations at Amherst, Union, and Hamilton colleges. This opposition to the secret societies received the name of the "Anti-Secret Confederation." The career of the confederation is significant. In 1859 the minutes of the Williams chapter contained the speeches of James A. Garfield, a vigorous leader of the opposition. At the time the Union chapter comprised practically all the students not members of the secret societies, and wherever it was represented, the confederation was at the height of its radical enmity to the fraternities. But even as early as 1858 it adopted Greek letters, and in 1864 it formally assumed the title of "The Delta Upsilon Fraternity" (39). In 1881 the term "Anti-Secret," long a misnomer, was replaced in the constitution by non-secret. It is a proof of the congenital character of the fraternity system in undergraduate life that its only organized undergraduate opposition should have gradually become in all respects but one a fraternity like its former enemies. Delta Upsilon has developed into a society with 10,000 members; though it would not be possible to introduce any element of secrecy within this organization, yet it exists in entire amity with its competitors. The fraternity claims that the influence of its early opposition was important in fixing the democratic character of the system.

The fraternities so far named, all founded in either New York or Massachusetts, and establishing a majority of their chapters in the Eastern states, are included in the group of "Eastern Fraternities." With them may be associated Delta Psi (8), founded simultaneously at Columbia University and New York University in 1847, — a conservative fraternity, selecting its members from families of social position; Chi Psi (17), founded at Union College in 1841, a society admirably organized from the start, and, like Delta Psi, conservative in the selection of its members; Zeta Psi (25), a vigorous fraternity founded at New York University in 1846, the first society to enter Canada, where it established a chapter at McGill University in 1883; Chi Phi (19), founded in 1854, and later comprising the three fraternities of that name, founded respectively at Princeton University of North Carolina and Hobart College (New York); and Theta Delta Chi (27), a fifth fraternity founded at Union College in 1848, and the first to establish the method of government by means of an executive council or "grand lodge."

As early as 1833, Alpha Delta Phi reached out to the West, establishing a chapter in Miami University, Oxford, Ohio, under the personal direction of the founder. Miami University played in the West the part of Union College in the East, and in 1838 presented the college world with Phi Delta Theta (73), following it in 1839 with Beta Theta Phi (73). These two fraternities have been characteristically "western," not only in origin, but in policy and methods. Neither has been in the least conservative; Phi Delta Theta has a roll of seventy-three chapters, not to speak of some twenty-four that have gone out of existence; and Beta Theta Pi is represented in seventy-three institutions, having given up its chapters in twenty-one more. Practically all the fraternities have now become national in scope. For most of them, national extension began about 1870, a date that may be set as the end of the tentative or struggling period of the fraternity system. The typically Western fraternities—now strongly represented in the East as well—have entered numerous smaller institutions, such as Allegheny, Roanoke, and Bethel colleges. The Eastern fraternities have usually been conservative in extending westward, confining their chapters to the larger or better known institutions. One Western college, Kenyon College, Gambier, Ohio, has from the earliest days boasted chapters of the principal Eastern fraternities.

Besides Beta Theta Pi and Phi Delta Theta, originating in the West, other fraternities have had so wide a Western extension as to center a great part of their activity in that section of the country. Such, for instance, are Phi Gamma Delta (57), and Phi Kappa Psi (44), both founded in 1848, at Washington and Jefferson College, Washington. Both societies extended first into the South and then into the West, with the occasional establishment of chapters in Eastern colleges. Miami also witnessed the founding of Sigma Chi (62), in 1855, the last of the "Miami Triad," which extended widely in the West and East. Its Southern chapters established before 1864 were all killed by the war, those at the universities of Virginia and Mississippi being later re-established.

The fraternities founded in the South include Sigma Alpha Epsilon (72), University of Alabama, 1856; Kappa Alpha (51) (not connected with the Northern fraternity of the same name), Washington and Lee University, Lexington, Va., 1865; and Delta Tau Delta (52), Bethany College, Bethany, W. Va., 1867. The early extension was limited chiefly to the South, and it is in this section and in the West that the fraternity has most strength. Delta Tau Delta amalgamated with the Southern society called "Rainbow" in 1886, a fraternity which had at the time four active and eight inactive chapters. Kappa Alpha (Southern) has placed its chapters in Southern colleges, with the exception of those in Leland Stanford University

and the University of California. Its chapters consequently include a number of inconspicuous colleges, but it has an admittedly high character of membership.

In 1854 members of the Kenyon chapter of Delta Kappa Epsilon erected a log cabin at a cost of fifty dollars, carefully plastering the wall with mud and equipping it with a stove and other utensils necessary for undergraduate revelry. This hut was the first chapter house. In the eighties the movement to build chapter houses became widespread, and to-day colleges have chapter houses of beauty, and in many cases of considerable value. At Columbia, for instance, the lodgeroom of the Delta Psi fraternity is furnished with carvings brought from Egypt. Memorial windows and gifts are not uncommon. No exact calculation is possible of the value of real estate held by the fraternities, but it probably exceeds four million dollars.

The feature of the college fraternities most strenuously opposed in the days when the system was on trial, their secrecy, is now generally agreed to be of small importance, and is usually characterized as amounting to little more than an insistence upon something similar to the privacy of home. To be sure, the fraternities, with the exception of Delta Upsilon, insist upon a system of passwords, more or less elaborate rituals, grips, and the like, but this side of the fraternity has practically ceased to be opposed. It probably has some effect in strengthening the bond between members, especially undergraduates. But it is far from being an essential characteristic.

The fraternities mentioned by no means exhaust the number of fraternities that are national in scope. The complete list, as given in Baird's *Manual of American College Fraternities* for 1905, numbers thirty-one national fraternities, besides seventeen sororities, or women's "fraternities," seventy men's "local" and forty-seven women's "local" societies, and as many as fifty "professional" fraternities, confining membership to students in schools of law, medicine, dentistry, music, or agriculture.

In addition to the societies already referred to, the following general fraternities with the date of their foundation and the number of active chapters may be mentioned: Alpha Chi Rho, 1895 (11); Alpha Sigma Phi, 1845 (8); Alpha Tau Omega 1865 (60); Delta Sigma Phi, 1901 (6); Kappa Sigma, 1869 (77); Phi Kappa Sigma, 1850 (26); Phi Sigma Kappa, 1873 (23); Pi Kappa Alpha, 1868 (28); Sigma Nu, 1869 (65); Sigma Phi Epsilon, 1901 (28); Sigma Pi, 1897 (5); Theta Chi, 1856 (6); Theta Xi, 1864 (13). For the club systems at Harvard, Princeton, and Yale, see the accounts of these colleges.

C. G.

**Sororities.**—Since fraternities arose largely by imitation, it is not surprising to find that similar organizations among women, sorori-

ties, began in coeducational institutions very shortly after the admission of women. The Greek names were, however, a late addition. Probably the earliest women's secret society was the Adelphean, established at Wesleyan College, Macon, Ga., in 1851, followed soon after by the Philomathean, 1852; the former became the Alpha Delta Phi in 1903, the latter Phi Mu in 1904. The first Greek letter sorority was the Chi Theta Delta, instituted at Troy Female Seminary in 1856 by chapters from the fraternity Theta Delta Chi. The Kappa Sigma was established at Elmira in 1856, and, unlike many other sororities, has had an unbroken existence since then; this was followed in 1886 by Phi Mu. The first national organization was the I. C. Sorosis, since 1885 Pi Beta Phi (43), founded at Monmouth College in 1867. The first Greek letter sorority was founded at De Pauw University in 1870, Kappa Alpha Theta (54). In the next few years a large number of Greek letter organizations followed: Kappa Kappa Gamma (35), at Monmouth College, 1870; Alpha Phi (35), 1872; and Gamma Phi Beta (14), 1874, at Syracuse University; Sigma Kappa (10), at Colby College (1874); Phi Sigma and Zeta Alpha at Wellesley College (1876). While many sororities were local only, many established chapters, most of which do not date back before 1880, while the greatest development has taken place in the last decade. There has been a strong tendency since 1906 for the better organizations to drop chapters which are not located in institutions of collegiate rank, and it has thus become more and more difficult for local societies to become affiliated in national sororities, which are those with five chapters or more. The government of the sororities is in the hands of the National Convention, which meets annually or biennially, while local and immediate questions are decided by the local executive councils, which are responsible to the convention. Chapter houses are not so common with sororities as with fraternities, although the movement to establish these is spreading rapidly, the first having been instituted in 1889 by Alpha Phi at Syracuse.

In addition to the associations already referred to, the following general sororities may be mentioned, with the dates of their foundation and the number of active chapters: Alpha Chi Omega, 1885 (14); Alpha Omicron Pi, 1897 (16); Alpha Chi Delta 1902 (15); Beta Sigma Omicron, 1888, (13); Chi Omega, 1895 (25); Delta Delta Delta, 1888 (33); Delta Gamma, 1872 (19); Kappa Delta, 1897 (14); Sigma Sigma Sigma, 1893 (6); Zeta Tau Alpha, 1898 (12).

**FRATERNITIES, HIGH SCHOOL.**—See HIGH SCHOOL FRATERNITIES.

**FRAUNCE, ABRAHAM.**—A literary man of the later Elizabethan age, born about 1558–1560. He was a fellow of St. John's College, Cambridge, 1580, and in 1583 a student of Gray's Inn. He was connected with Edmund Spenser, Sir Philip Sidney, and Thomas Watson. From the point of view of the history of education, the importance of Fraunce rests on his *Arcadian Rhetorike*, 1588, and the *Lawiers Logike* of the same year. The former work is illustrated by examples in half a dozen languages, and is preceded by a dedication in all of them, which is characterized by Professor Smith as "a piece of schoolboy conceit." In the same year Fraunce published: *The Lawiers Logike, exemplifying the precepts of Logike by the practise of the Common Lawe.* In this work Fraunce drew his illustrations from poetical works in French, Latin, and English, as he did in the *Arcadian Rhetorike*, and also from the common laws of England. Fraunce's *Rhetoric* and *Logic* cover much the same ground, and his significance educationally lies in his advocacy of the new views of Ramus, and his application of Ramus' (*q.v.*) methods of illustrations of rhetoric and logic by citations from English poets, and from continental modern poets—thus bringing modern and contemporary authors into direct comparison with the standards of classical writers as literary models in rhetoric and logic. At the same time Fraunce regarded the classical writers as the models for original verse, and himself wrote his poetry in hexameters. (See *Cambridge History Literature*, Vol. IV, p. 131.) For an account of the struggle in the university between Aristotelianism and Ramism, the Preface to the *Lawiers' Logic* is an important historical document. Fraunce also wrote a work on emblems and symbols in Latin (1588).

**FREDERICK COLLEGE, FREDERICK, MD.**—An institution established in 1763 for the education of boys, and chartered as a college in 1830. Most of the work is preparatory to entrance to college, although the degrees of A.B. and S.B. are conferred by the institution. There is a faculty of nine members.

**FREDERICK II, THE GREAT, OF PRUSSIA** (1712–1786).—Education formed no small part of the benefits conferred on his country by this truly great monarch. Into the details of his own education under the tyrannical régime prescribed by his father it is not necessary to enter. They have been vividly described by Carlyle, Macaulay, and

Freytag. How far Frederick's views on education were colored by his early experiences it is difficult to say, but that he fell under the influences of the educational thought of the Enlightenment there can be no doubt whatever. Wherever he touches in any degree on the subject, and in his letter *Sur l'Éducation*, written to Baron von Münchhausen, he insists on the exercise of judgment, on cultivation of the understanding, on thinking for one's self, on the development of the power of reasoning as the highest aim of education. *Faire bien raisonner*, he demands. Not only intellectual ability, but moral perfection, depends on reason. These principles he considers applicable to the three branches of education, elementary, secondary, and higher. The chief fault which he had to find with the schools of his period was the amount of rote learning, the insistence on memory training, and an absence of independent intellectual activity on the part of the pupils. Early in his reign he turned his attention to elementary education, and by regulations of 1740, 1741, and 1743 dealt with the question of support of schools established in the villages of Prussia. The province of the elementary schools was assigned to the clergy generally and to the Lutheran High Consistory. The real and normal school established by Hecker (*q.v.*) received constant encouragement from the royal patron, who in 1750 ordered that teachers for the schools on the royal domains and administrative villages should be taken from this school, which thus became a center of elementary education as well as of the industry of bee-keeping and the culture of mulberry trees. In 1763 the famous General School Regulations for the Country (*Generallandschulreglement*) were issued, providing for compulsory education between the ages of five and fourteen, for the amount of fees and fines, for the support by landed proprietors and tenants, for the appointment of satisfactory teachers, for textbooks and supervision and examination by the clergy. Although this measure may, in practice, have turned out to be nothing more than a pious wish, it laid the foundation of the Prussian system of state education. In 1765 a supplementary measure, drawn up by Felbiger (*q.v.*), was passed for the Catholic section of the kingdom. At the instigation of the King, school funds were established in Pomerania and the Kurmark. It is true that much of the good work already begun was frustrated by the personal permission of Frederick, given in 1779, to employ veteran soldiers in the schools; but the foundations for a better future had already been laid.

Secondary education also received the attention of the King, whose ideas were put into effect by Von Zedlitz (*q.v.*), whom he appointed chief of the ecclesiastical department and school affairs in 1771, and by such practical men as Meierotto and Gedike (*qq.v.*). Himself lacking

a knowledge of the classics, denied him by his august father, he yet emphasized the need of it in the gymnasium, not for its own sake so much as for a basis of approaching the vernacular. The despised vernacular, too, was given a place of honor in his scheme, and with prophetic insight he saw its possibility as a literary instrument. History, especially German, was to be employed to train the judgment and character; religion was to form a basis for morals; but above all reason was to be developed. (*Schreiben von 5 Sept. 1779, an den États-Minister Freiherrn von Zedlitz in Œuvres*, XXVII, Pt. 3, p. 253.) When the Pope issued the bull abolishing the Jesuit Order in 1773, he refused to recognize it in his kingdom, for he felt that, whatever the shortcomings of the Order, the Jesuit schools were the only kind available for his Catholic subjects.

In higher education he encouraged the development of academic freedom at the universities (*q.v.*), and reestablished with great pomp the *Akademie der Wissenschaften* in Berlin. But his chief interest was in the establishment of an institution where a selected group of young nobles, whom he regarded as the pillars of the country, might be trained for public careers in the army and diplomatic service. His ideal was the Greek ideal of a soldier, statesman, and scholar. After the Seven Years' War he established the *Académie des Nobles*, and drew up the plan of instruction himself (*Instruction pour la Direction de l'Académie des Nobles*). The central aim, again, was to be the formation of judgment which could be turned to any subject; logic, rhetoric, letter writing, history, geography, disputation, philosophy, a knowledge of classical antiquity (through modern works, however), of literature and of the development of civilization were to form the curriculum for the fifteen nobles who were selected for the academy.

In these numerous ways were manifested in an altogether remarkable degree the interest of the "Father of his Country" in the educational advancement of his subjects, which paved the way for the educational leadership which the Prussian kingdom was to hold in a later generation.

**FREE LECTURE SYSTEM.** — See LECTURE SYSTEMS, PUBLIC.

**FREE PLAY.** — See PLAY.

**FREE SCHOOLS.** — The true and only meaning of "free school" is that of a school free from tuition fees. This is the definition in Dr. Johnson's *Dictionary*, "Free, without expense, by charity, as a Free School, a school in which learning is given without pay." But since 1865 the currently accepted explanation of the term in educational circles in England has been that it means free in any sense but that, and, for choice, means free from ecclesiastical authority. This wholly unhistorical and untrue explanation was accepted simply on "authority" because put forward by that great classical scholar and producer of classical scholars, Dr. Benjamin Hall Kennedy, headmaster of Shrewsbury School for a generation, 1836-1866. At the time of the Public Schools Commission in 1862 the question was a burning one whether the public schools, all but Winchester specifically, founded as free grammar schools, open to all comers without fees, were not committing a breach of trust in charging fees to their pupils, and whether the poor of the towns of Harrow, Rugby, and Shrewsbury were not being robbed by this imposition in favor of the rich from a distance. Harrow and Rugby were then little more than villages, but Shrewsbury being a town of considerable size, the question assumed its most burning and importunate form there. So Dr. Kennedy wrote a paper, published and practically endorsed by the Commission, in which he asserted or implied, in the first place, that the term Free School was due to Edward VI's numerous foundations of schools under the title of *Libera Schola Grammaticalis Edwardi Sexti* and that *libera* never meant "gratuitous" in classical or medieval Latin, and that it could not mean "gratuitous" in Edward VI's days because all schools were gratuitous; "for of schoolkeeping as a profession no trace is to be found, while in the conventual, chapter, and collegiate schools instruction had always been gratuitous to the poor." He asserted

that *libera* meant free from jurisdiction of a superior corporation, and in this case of ecclesiastical corporations. Every one of his dicta can be shown to be absolutely false. First, as to classical Latin, there are three passages in Livy alone (xxx, 17; xxxv, 23; xlii, 6) in which *libera* is used in the sense of free from payment; all referring to the grant of *cedes liberae*, or free lodgings at Rome to foreign ambassadors; while the same author records one of the terms of peace with Antiochus in 189 B.C. as being that the cities of Asia which had been tributary to him were to be "free (*liberae*) and exempt," i.e. from payment. It is from this and phrases like this that the medieval meaning of *libertas*, *libera*, and *libere* was derived. The most important sign of subjection to a superior, and the most lucrative, was the payment of tribute, toll, or fees. So *liber homo* was the free man, free of doing service in kind, the *liber burgus* was the free burgh, the *liberi burgenses* or free burgesses of which were free from toll in the borough market, and by virtue of royal charters free throughout the realm. A Liberty (*libertas*) was a district free of toll, as in a charter of 1129, "All those who dwell in the said Liberty, who owe toll to me shall be exempt from all tolls," and as in 1200 when King John "granted the freedom (*libertatem*) of my manor of Estaintot from all manner of customs (i.e. customary tolls) and services." The royal free chapels, such as St. George's, Windsor, and St. Stephen's, Westminster, were chapels free from visitation by the bishop and archdeacon, and disputes about their freedom always arose on the question of paying the episcopal or archidiaconal fees for the visitation. So naturally a free school meant a school free of fees. As to schoolkeeping not being a gainful profession and fees not being charged for teaching, there is abundant evidence that precisely the reverse was the case. The archdeacon of Bury St. Edmunds, writing c. 1075, gives the most emphatic, because casual, evidence that tuition fees were charged in schools, by telling us that King Canute, when he came to a noted minster or castle, sent there to be brought up at his own expense any boys he found, either freemen or among the cleverer of the poor. If there were no tuition fees, what was the expense? A century later Abbot Sampson, immediately after his promotion, gave a living to a certain Master Walter because his father, when schoolmaster, while Sampson was a poor clerk, granted him admission to the school without any charge, by way of charity. Shortly after, the abbot bought a stone house in Bury town and gave it to the school on condition that four clerks (i.e. schoolboys) should be admitted free, "as every scholar whether able or not had before this to pay 1*d.* or 1½*d.* twice a year." A few years later, about 1198, he endowed the school with an annuity of £2 a year in gratitude for his own free tuition,

that forty poor clerks might be free of all payment of money (*denariorum*) to the master for their instruction. There must still have been a large number of paying scholars, as in 1289 and in succeeding centuries the thunders of the Church were directed against those teaching school in Bury without the endowed grammar schoolmaster's license. There was obviously no reason why they should teach or be objected to for teaching, if none of them got tuition fees from it. Perhaps the most striking proof of schoolmastering being a gainful profession is the complaint to Parliament in 1447 of four London parsons against the monopoly of St. Paul's and the two other schools of London. They urged that "while there had been a great number of grammar schools . . . in divers parts of the realm," they were now decayed, so that children instead flocked to London. "Wherefore it were expedient that in London were a sufficient number of schools and good informers in grammar, and not for the singular avail of two or three persons grievously to hurt the multitude of young persons;" for where there is "grete nombre of lerners and few techers and all the lerners be compelled to go to the same fewe techers, the maisters waye riche in money and the lerners pouere in connyng as experience shewith." Toward the end of the fourteenth century, a movement began of which Winchester College in 1382 was an early example on a large scale for the establishment of schools free for some or all who came to them.

On Oct. 20, 1384, Katherine, Lady Berkeley, widow of Sir Peter Vele, "attentively considering that the purpose of many desiring to be informed in grammar, the foundation of all the liberal arts, is daily frustrated and defeated by poverty and want of means," gave lands at Wotton-under-Edge, Gloucestershire, for building a schoolhouse and maintenance of a master, with two free scholars of the art of grammar, a sort of pupil teachers, to "govern and inform all scholars coming to the same house or school for instruction in this art, without taking anything for his trouble from them or either of them." This the Chantry Commissioners of Henry VIII describe as "the Katheryn Vele Fre Schole" and those of Edward VI "a Free Schole of the foundation of one Lady Katherine Veele — for a mayster to teach gramer freelye."

That such provision was needed, if the school was to be free, is clear from *Piers Plowman* at this time putting into the mouth of "My Lady Meed" the remark "Men that teach children take of them meed." By ordinances made July 14, 1414, for the Grammar School and Song School, founded on the Palace Green at Durham, by Thomas Langley, Cardinal-Bishop of Durham and ex-Lord Chancellor, two chaplains were "perpetually bound to teach school, one in grammar, and

other in song, in the city of Durham, and diligently to teach and instruct all willing to learn or study under them in the said sciences, the poor indeed (*gratis*) for the love of God, if they or their parents humbly ask it, but taking from those who themselves, or by their friends, are willing to pay the moderate fees accustomed to be paid in other grammar or song schools." The endowment at first was only £2 a year, so that fees were a necessity, though it was increased to £10 a year in 1440 in virtue of directions contained in the Bishop's will. The Chantry Commissioners of Henry VIII describe this foundation as "two Free Scooles, the one of Grammar and the other of Songe." Yet there was no idea of its being independent of ecclesiastical jurisdiction, for the stipend was paid out of the episcopal revenues, and the bishop appointed the masters. The stipend is still paid to the master of the cathedral grammar school, founded by Henry VIII as part of his new cathedral foundation. In 1437 William de la Pole, Earl of Suffolk, obtained license to found an almshouse at Ewelme, near Oxford. The statutes, in English, made some ten years later, provided a "preste," "to whose office it shall longe . . . to techie and inform childer in the faculty of grammer, provided that all the childer of oure chapelle, of the tenauntes of our lordshyp of Ewelme and of the lordshypes pertaining to the sayde almehse howse . . . *frely* be taught without exaction of any scole-hire."

On Oct. 20, 1440, King Henry VI founded Eton College for twenty-five "poor and indigent scholars to learn grammar" with "one master or teacher in grammar, whose duty it is to teach the said scholars and others whatsoever and whencesoever from our realm of England flocking to the said college in the rudiments of grammar, *gratis*, without the exaction of money or anything." The *gratis* of the King exactly translates the "frely" of the earl.

Gryndours Chantry, or Newland grammar school, in Gloucestershire, was founded under license in mortmain of Feb. 28, 1445-1446, for "an honeste and discrete preste beinge sufficiently lerned in the arte of gramer to kepe and teche a grammer scole ther *half free* for ever; that is to saie, to take of scolers lernynge grammer *8d.* the quarter and of other, lernynge lettres, and to rede, *4d.* the quarter, within a house there called the chauntre house or scoole house."

The Chantry Commissioners reported in 1546 that the "incumbent and scolemaster . . . is of good lernynge . . . the scole nowe beinge well haunted and furnished with scolers, and hathe ben allweyes." The people asked for its continuance, "or els hit shalbe a greate lose and discomoditie to all the countrie thereabouts, for that there is not any other Gramer Schole, free nether otherwise, not by a

great distance." This case is a crucial one. It shows that the people of 1446 and of 1546 equally thought that a free school meant a school free from tuition fees, that tuition fees were normally paid in grammar schools, and that a half-free school was one at which half the customary rate of tuition fees was paid. In 1472 John Gardiner said, by his will in Latin, "I wish a grammar school to be freely (*libere*) maintained in the towne of Lancaster." He wished it made free. His executors, by an ordinance in English, of Mar. 1, 1500, laid down that the master should be "a professed grammarian, keeping a Fre Schole teaching and informing the childer unto the most profit, nothing taking therefor."

In 1483 a private act was passed as to Acaster College, near York, which recited that Robert Stillington, Bishop of Bath and Wells, had founded it for a provost and three fellows, who were "3 dyvers maisters and Informatours, . . . oon of theym to teche grammer another to teche musyk and song, and the third to teche to write and all suche thing as belonged to scrivener craft . . . severally, openly and freely, without exaction of money or other thyngs of any of their suche scholers and disciples." In like manner, by deed in Latin, Feb. 1, 1482-1483, Thomas Rotherham, Archbishop of York, founded Jesus College at Rotherham, for a provost and three fellows, "the first a doctor of grammar, the second learned in song, and the third for those who did not wish to attain the dignity of the priesthood, learned in the art of writing and accounts, to teach those coming to our college in grammar, song, and writing, without exaction of money or other thing." The Chantry Commissioners of Henry VIII reported them as "three scholemasters to teche all chylidren frely," and speak of "the three fre scoles"; and the Commissioners of Edward VI also mention them as "three scholemasters of free scholes." They were certainly not free of ecclesiastical control; the provost was bound to be a priest, and the archbishop was visitor and appointed him.

On Jan. 25, 1502-1503, Sir John Pereyvale, Merchant Taylor and ex-Lord Mayor, by will founded a chantry in Macclesfield, and directed that the "preest shall always kepe a Fre Gramer Schole, teching there gentilmens' sonnes and other good memies children of the towne and contre thereabouts." Here is the full phrase forty-five years before Edward VI, and, as the master was also a chantry priest, he was certainly not exempt from ecclesiastical authority.

On Aug. 20, 1515, Hugh Oldham, Bishop of Exeter, ex-Clerk of the Hanaper in Chancery, gave endowments, by a deed in Latin, to provide at Manchester "a fit person able to be a schoolmaster, to freely (*libere*) teach and instruct boys and infants in grammar according to the use and form of grammar now taught in the town of Banbury . . . without anything

taking therefore except his salary above limited"—*viz.*, £10 a year. On Nov. 7 following, two of the trustees acknowledged the receipt of £50 from Oldham "towards the foundyng of a free scolle . . . to begin on Monday next after the Epiphany . . . comyng." So here we find the founder himself translating *libere docendum* into "a free school"; while in another Latin deed of 1523 Lord de la Warr recited that he had granted the mills, which formed the chief part of the endowment, only because it was for a free school, *in usum libere scole*, of Manchester. This school was by no means free from ecclesiastical control, being under the collegiate church of Manchester and other church dignitaries.

At Berkhamsted the inhabitants, in concert with Dr. Incent, a Fellow of All Souls College, Oxford, and Dean of St. Paul's, in 1523-1524 assigned the lands of the Brotherhood of St. John the Baptist, while the dean, like his predecessor, Colet, gave the whole of his paternal inheritance, including a mansion house called "Incent's," in the town, for the support of a school. Fearing the dissolution of brotherhoods, Incent obtained letters patent of Oct. 14, 1541, granting him license to found "one chantry . . . and also one Free Schole within the towne . . . of one mete man being a scholemaster and one other mete man being an ussher for the teching of children in grammer frely withoute any exaction or request of money for the teching of the same children, not exceeding the nombre of 144," and to acquire lands up to £10 a year value for its support. The corporate name was "The Master Chapleyn or Chapleyns and Ussher of the Fre Schole and Chantry of Dean Incent's in Berkhamsted." So far from the "Free Schole" meaning freedom from ecclesiastical control, while the King was to appoint the master, the Dean of St. Paul's was to "name the ussher and chapleyns." The Chantry Commissioners of Edward VI reported it "a Fre Schole," but the foundation was declared void. A private act of Parliament, passed in 1549, restored the endowment, excepting some parts sold to pay costs, and re-incorporated it as "The Master and Usher of the Free School of King Edward the Sixth in Berkhamsted." The act explained what it meant by "free" by repeating almost verbatim the words of Incent's charter, "for the teaching of the said children to the number aforesaid (144) freely without taking any stipend for the teaching of the same, either of them or of any of their parents or friends." There can hardly be a case which shows more emphatically both that the so-called Edward VI free grammar schools were only his in so far as his name was substituted for that of the original founder, and that they were free in the simple sense of free from tuition fees.

We may add to it that of Stourbridge, where a stipendiary priest "stood charged to teche the pore men's children of the parishe frely,"

and "bath always used and yet doth use to kepe a scole." The lands of this school were confiscated under the Chautries Act in 1548. But the court which managed the confiscated lands ordered on June 1, 1550, lands of other chantries to be granted "for the free teaching of children within the town," and the legal re-foundation, though delayed, was made by letters patent of June 19, 1553, in which the school is called the *Libera Scola Grammaticalis Regis Edwardi Sexti*, or Free Grammar School of King Edward VI, for the instruction of boys and youth in grammar. At Shrewsbury itself it is not known exactly how the school, — which certainly existed there in the early eleventh century when Ordericus Vitalis began his education in it, while in the thirteenth century its master occurs as a Papal delegate, to act as a judge on an appeal to Rome, — was maintained. But it was apparently in connection with one of the collegiate churches in the town. In 1549 the town accounts show £20 paid "for buying a free school (*liberas scolas*) to be kept within the town," and on Feb. 13, 1552 (which Dr. Kennedy inaccurately made 1553), a charter was granted in the same words as at Stourbridge for a *Libera Scola Grammaticalis Regis Edwardi Sexti*. So little was this school free from ecclesiastical control that its statutes were to be made, as usual in the charters of Edward VI and Elizabeth, with the consent of the Bishop of the diocese for the time being. Dr. Kennedy found that under statutes made in 1578 a scale of admission fees was imposed from 10s. on the son of a lord down to 4d. on the son of a burgess unless he was "not of ability," when he was to be free, he argued that, if a free school meant a gratuitous school the statutes were in contravention of the charter, and therefore *Libera* in the charter did not mean gratuitous. But this is due to not seeing the distinction between tuition fees and entrance fees. At the free school of Manchester (1515) following St. Paul's (1510), the founders themselves imposed admission fees as not being counter to the freedom of the school. So in the free grammar school of Hexham fees were imposed on those outside the parish, to provide for flogging instruments; "the schoolmaster's ferules shall be 4s., 1s. for every quarter day." At Hertford in 1606 the founder said that the parent of every free scholar "shall pay 2d. quarterly for brooms and 12d. for the whole winter for fire and candle." A free school meant free teaching, and nothing more. As a free pass to the theater means a free seat only, and does not entitle one to free cloakroom, free program, or free refreshments, so freedom from tuition fees did not include free birching, free books, free fires, free lights, or freedom from admission fees paid for entering a boy's name.

Between twenty and thirty free grammar schools of Edward VI were founded by charter of Edward VI, and some eight under Philip

and Mary. They were apparently regarded as successful institutions, since about 120 were founded in the forty-three years of Elizabeth; the great majority, as in previous reigns, being not new foundations, but preëxisting free schools, made free, revived or reëndowed. The same process went on under James I and up to the end of the seventeenth century. During the Commonwealth (1649-1660) a noticeable change took place in the greater importance given to English grammar and mathematics and writing. But the free school was still in vogue. Even as late as 1726 the Rev. Roger Kay endowed a free grammar school at Bury in Lancashire, free for the youth born in the town and (like Walter of Merton nearly 500 years before) free for his next of kin wherever they lived. By his statutes he expressly explained that while saying the school was free, "this was not to debar the master and usher from that common privilege in all Free Schools of receiving Presents, Benevolences, Gratuities, etc., from the scholars their parents and friends," and "besides the usual cock-penny at Shrovetide," he ordered two days in the year for the free scholars "to present the master with a piece of money." He fixed the amounts of this present at 2s. 6d. to 5s. for the master and 1s. to 2s. 6d. for the usher; and this was besides 2s. 6d. entrance fee, and 6d. a year for repair of the school windows. In 1740 he extended the freedom to all living in the parish, wherever born. This foundation was placed under the tutelage of five parsons *ex officio*, so that ecclesiastical control was not diminished, though the rigor of freedom from tuition fees was clearly being undermined by the practice of voluntary donations, which by custom had become compulsory. At Winchester this custom had prevailed so far that, in spite of the express words of the statutes forbidding any payment, every "poor and needy scholar" paid £10 a year to the headmaster. Though in 1776 the custom was solemnly condemned by the Visitors as a grave scandal, the only result was that words were added to the school bill so that the item appeared as "gratuity, if allowed." At last a tender-conscience headmaster, Dr. Goddard, in 1834, gave £25,000, the income to be paid to the headmaster in lieu of the gratuities, because "it has been such a distress of conscience to receive the money I am determined no Headmaster in future shall suffer the same."

Oddly enough, while in Queen Anne's time the free schools received a great accession from the foundation of charity schools (in which not only free education, but free clothing, and in many cases free board and lodging, was given), in the great development of elementary schools in the latter part of George III's reign (1780-1820) fees, though only 1d. or 2d. a week, were imposed.

But meanwhile the free education in the grammar school had become a burden instead

of a privilege. When the means of traveling increased, the larger schools, from Winchester and Eton downwards, in which a fairly substantial "gratuity" was imposed by custom for the education and large payments were exacted for boarding, attracted all the richer classes into a few big schools. These began to arrogate to themselves the exclusive title of Public Schools. In the smaller grammar schools fierce contests arose as to the extent of the freedom from tuition fees.

In process of time, as the value of money had fallen, the endowments ample for the single master and usher for purely classical instruction of classes of thirty-five to fifty proved wholly insufficient for teaching the numerous additional subjects, French, English, mathematics, and science, which necessitate numerous masters and small classes; the free school became an impossibility. At the end of the eighteenth century the Court of Chancery met the difficulty by holding that the freedom only extended to the teaching of Latin and Greek, a decision which had the remarkable effect of excluding from the schools the poorer classes who did not want to learn classics and did want to learn the other subjects, especially English and arithmetic, for which fees more or less heavy were imposed. Hence the cry of robbing the poor and breach of trust, for which Dr. Kennedy devised his successful but wholly false answer. The courts never adopted it. But the difficulty which the law courts were unable to solve was met by the establishment by Parliament, from 1862 to 1874, of commissions with legislative powers, the public schools commission, the endowed schools and the charity commissions, which swept away the pretense of free schools, imposed fees of substantial amounts for education, retaining freedom only for a certain number of free scholars, generally from a limited area, selected by competition. After the elementary schools were made free by state intervention, and large powers over schools were given, in 1896 and 1902, to local authorities, a movement for free secondary schools again began. If the State or the locality is prepared to find the necessary funds by grants increasing with the demands of the time and the numbers in the schools, it can of course ensure freedom. But it may have to consider whether the schools which it makes free will attract the pupils it wishes to attract. In the eighteenth and early nineteenth centuries, where the freedom of the schools was successfully upheld by popular pressure and the magnitude of the endowment, the schools soon fell into decadence, as the richer classes deserted them for fee-paying schools, where they could get the variety and teachers they wanted; and the poorer ceased to value what could be had for nothing, where they only met each other, and where there was no real inducement for the teachers to do their best. Whether in the

future these difficulties can be overcome remains to be seen. By the Secondary School Regulations (1909) all fee-charging schools, to qualify for the higher government grants, must, among other conditions, offer free places to pupils entering from public elementary schools, the number ordinarily being 25 per cent of the total number of pupils admitted to the school in the previous year. As a result of this measure, and the rise in the cost of maintenance and equipment of secondary schools, fees appear at present to be rising.

A. F. L.

**AMERICAN USAGE.** — In colonial America the term appears frequently, and has led to various interpretations, as in England. While, as in England, the term has been interpreted by students in a variety of ways, a careful examination of the local records, which are now available in print, indicate that the term "free" was not used in connection with schools except in the sense of free from tuition charges, though such schools were not always under the direct control of nor directly supported by the government. In other words, a free school was not necessarily a public school in the later use of the term. The earliest evidence we have is that of the Boston Latin School, 1635, when it is stated that the richer inhabitants gave "towards the maintenance of a free schoolmaster for the youth with us." A few years later, 1644, at the neighboring town of Dedham, the inhabitants "did with unanimous consent declare by voate their willingness to promote that worke promising to put too their hands to provide maintenance for a Free Schoole in our said Towne." This was probably an elementary as well as a Latin grammar school. But there is no question but that the term was also used in connection with the elementary school, as is indicated by the following excerpt from the Boston records of 1686. "The same day it was voted by ye inhabitants yt the same Committee with ye Select men consider of & pvide one or more Free Schooles for the teachinge of Children to write & Cypher within this towne."

In the other colonies the term was often used, but most frequently in connection with the Latin grammar schools. As most of these had endowments of some character, or were supported by contributions, they were usually "free." But even here the use of the term was sometimes ambiguous, as is indicated by the contemporary reference of Beverly, when he states that there were "tracts of land, houses, and other things granted to free schools for the education of children in many parts of the country; and some of these are so large that of themselves they are a handsome maintenance to a master; but the additional allowance which gentlemen give with their sons render them a comfortable subsistence. These schools have been founded by the legacies of well inclined gentlemen. . . . In all other

places, where such endowments have not been already made, the people join and build schools for their children, where they may learn on very easy terms." So it is evident the tuition was paid in "free schools," but only by children of wealthy gentlemen. The term "free education" was also somewhat ambiguous, but no doubt it is used here in the sense of "liberal" or higher education. In the statutes of the Southern colonies, relating to the education of orphans, the following phrase occurs repeatedly: "But if the estate be so mean and inconsiderable that it will not reach to a free education, then the orphan is to be bound out to some manual trade till one and twenty years of age," etc. (Virginia, Act II, 7th of Commonwealth, December, 1656). This is substantially as it appears in subsequent acts. Previous to this time, similar enactments use the phrase, "extends not to give them breeding," so that "free education" and "breeding" are evidently used to signify liberal education.

In the early nineteenth century free school becomes synonymous with charity school, and though it was used to avoid the opprobrium of the other term, it has come to have much the same stigma attached to it. Thus in 1805 the "Free School Society" was established in New York City "for the education of such poor children as do not belong or are not provided for by any religious society." But in 1826 the title was changed to "Public School Society," to avoid the opprobrious term and also to permit charging tuition for pupils who were able to pay. But this charge only accentuated the social discrimination, and after the very existence of the society was threatened, all tuition charges were abolished and the schools again became free in 1832, but retained the term "public" in preference to "free." It was ten years more before the city itself took up officially the responsibility for schools, and not until 1853 that the schools of the Public School Society were turned over to the city school board. The discrimination caused by tuition charges survived longer in rural regions than in the city, and were not finally abolished by statute until 1867, after an agitation of three or four decades of free schools. In some states the final establishment of "free" schools, as contrasted with public schools, did not occur until after this date, and in general, outside of New England, this stage of compulsory freedom from tuition charges was not reached until after the Civil War period.

See, for details, the articles on the various states of the American Union; and on the educational system of the various countries; also, COST OF EDUCATION; COLONIAL PERIOD IN AMERICAN EDUCATION; FEES; PUBLIC SCHOOLS. P. M.

**FREEDMEN'S BUREAU.**—A section of the War Department established at the time of the Civil War in the United States, to deal with the different phases of the negro problem which then cropped up. A Bureau of Emancipation was proposed in Congress in 1863, but failed to be enacted; in the same year a committee of inquiry suggested a temporary bureau "for the improvement, protection, and employment of refugee freedmen." A bill passed by Congress in 1864 for the establishment of a Bureau of Freedmen in the War Department came to nothing, but in February, 1865, a bill for the establishment of a Bureau of Refugees, Freedmen, and Abandoned Lands was passed, and this was placed under the War Department. It was to be maintained throughout the war and one year thereafter, and was to have "the supervision of and management of all subjects relating to refugees and freedmen." In 1866 its powers were more fully defined and extended. The work was placed in charge of a chief commissioner, General Oliver O. Howard (*q.v.*), with power to appoint assistant commissioners in different districts. One of the chief objects of the Bureau was the establishment of schools, and one of the earliest acts was the introduction of school teachers from the North. By the extended powers granted in 1866, Confederate public property could be sold and used for educational purposes. The general work of the Bureau came to an end in 1869; but the educational work was carried on beyond that date. The Bureau coöperated largely with benevolent associations, and so far as was possible encouraged support of colored schools by the freedmen themselves. State superintendents of education were appointed. The *Ninth Semi-Annual Report on Schools for Freedmen*, issued in 1870 by the General Superintendent of Schools of the Bureau, J. W. Alvord, gives the following figures on the progress of education of the colored people. There were 2677 day and night schools, with 3300 teachers (of whom nearly 1800 were colored), and 149,581 pupils in attendance. The freedmen maintained wholly or in part 1324 of the day and night schools, and

owned 592 school buildings. The average attendance of pupils was 78 per cent; \$61,513.03 was paid in tuition by the freedmen, who also paid a large proportion of teachers' salaries. Thirty-eight high schools, with 3834 pupils, were in operation, and of these, eleven were colleges and universities; there were in addition thirty-three industrial schools, with an attendance of 776 pupils. During the five years of its work, the Bureau spent \$6,513,955.55, of which a considerable part went to educational purposes. \$750,000 of this sum came from the freedmen themselves. The Bureau thus helped to give the negro opportunity for free education, and also familiarized the South with a system of public elementary education. In addition, the institutions for higher learning, if they did not receive material support, at any rate had the full encouragement of the Bureau, and it was at this period that Atlanta, Fisk, and Howard Universities and Hampton Institute were established.

**FREEDOM, ACADEMIC.** — The freedom to teach in higher institutions of learning well-thought-out principles and demonstrated truth, or to direct the search for these without the interference of political, bureaucratic, or religious authority. In recent times restrictions upon this freedom more frequently arise through limitations placed upon the individual instructor by the administrative authorities of the university or college itself. In its origin the right was simply that of "internal jurisdiction" granted by Pope or monarch. (See Universities.) In modern times the right and the problems connected with its maintenance have assumed quite different forms.

In the main, the question of academic freedom falls within the struggle for freedom and thought, *i.e.* of scientific inquiry. In part, it belongs to the political struggle for the right to free speech and publication, a movement more closely connected with the scientific struggle, however, than is usually recognized. If ideas and scientific information were so abstract and impersonal as to have no bearing upon social practice, or if social institutions were so plastic and flexible as to respond easily to every intellectual change, freedom of thought and expression would not have to be bought at a great price. But since social life rests upon a body of customs, or *mores*, which have great inertia and which tend to persist simply because they have existed, and which resist change, the innovator, the inventor, the reformer, the prophet of change have been regarded with suspicion and dislike. Moreover,

ideas which, in their origin, were quite theoretical or purely intellectual, become a part of men's general intellectual attitude, and share in the ossification characteristic of habit. Thus astronomical and geographical ideas that, taken by themselves, had no direct moral or social meaning, became so fused with mankind's religious and moral conceptions that at the Renaissance the changes of belief incident to a progress of those sciences seemed to many like an attack upon the foundation of the fundamental moral and religious convictions of mankind. The same situation recurred, though with less intensity, in the sciences of life upon the promulgation of the Darwinian theories. Since schools and colleges are social institutions, supported directly and indirectly at public expense and appealing to the general public for students, features of the general conflict are inevitably reflected in them.

By the nature of the case, disputes regarding infringement of the liberty of the teacher to teach or discuss doctrines hostile to the customary beliefs of the community arise in subjects and parts of subjects that are scientifically novel. This means that scientific opinion is divided; or, if the new doctrine is one of great importance, that the weight of scientific authority is hostile. Then the academic institution can allege that the objectionable doctrine is not sufficiently well established to justify its classroom promulgation. In such cases, it is claimed that the teacher who introduces it is not using his right to liberty of intellectual thought and expression, but is rather engaged in a propaganda of his private opinions. Barring the cases (more often found in America than elsewhere) of supposed interference by a founder or large benefactor in matters where he happens to have strong personal interests, it will be found, accordingly, that the question of violation of academic freedom comes up in sciences and topics that are in a condition of formation or rapid transition — as the historic portion of this article demonstrates. One can hardly conceive the question now arising in those portions of mathematics, physics, chemistry, etc., that are generally recognized to be established.

Regarding questions that fall within the debatable middle grounds (questions with a bearing upon economic, political, moral, or religious practice and belief) the following principles may be laid down. (1) There is a marked difference between institutions which lay claim to a genuine university or scientific status, and those which exist for the sake of upholding a set of tenets agreeable to a certain class. What would be a violation of academic freedom in the former case is not necessarily so in the latter. But it should be made clear that the latter type of institution does not claim to exist for the discovery and teaching of truth impartially, but for the propaganda of certain doctrines — an admission that few institutions

at present are willing to make about themselves. (2) The relative maturity of the students is a point of obvious moment. Certain discussions that would be perfectly proper, that indeed are educationally indispensable, with students of a certain degree of progress might be inadvisable with younger pupils. The attempt to make a fixed line of demarcation between colleges that are simply teaching institutions and those that make a point of research is not, however, justified. The results and spirit of research are such a general part of the intellectual life of the present day that an institution which made such a distinction a criterion of what was allowable and unallowable in the classroom would confess to a dogmatic and unscientific trend. (3) There is an obvious difference between teaching as final what is still under discussion among scientific men themselves, and presenting the same matter impartially to students, though with a definite indication of what the instructor's own views are. An institution that even indirectly discourages the latter course on disputed economic and sociological points virtually surrenders its claim to be conducted in the spirit of a university, whose mark is love of truth. Even the expression of individual opinion on matters beyond the possibility of immediate scientific settlement is better than an atmosphere which restricts presentation to the conventionally settled aspects of a subject. As a matter of fact, where free discussion is permitted, the student is pretty sure to come into contact with varying views upon a topic so that the danger of being misled by a one-sided presentation of a matter is much less than it seems. This mutual offsetting and supplementing of erroneous ideas by one another has been proved in political experience to be an adequate ground for permitting free speech and publication, and the same reason applies to education with little qualification. Much of the popular misapprehension as to the "danger" of free discussion of such topics as, say, socialism in college classrooms, arises from failure to realize the extent to which an atmosphere of free discussion carries with it its own protection against unbalanced propagandism. (4) Experience shows that in the present state of things the menace to academic freedom is indirect rather than direct. That is to say, there is little likelihood that any trained independent thinker will have his ideas suppressed. But American colleges have undergone a very rapid expansion, demanding great increase in material resources; the proper equipment of library, laboratories, museums, etc., being very expensive. This has led both to an aggrandizement of administrative authority and to a direct dependence upon the wealthy men from whom the necessary endowment must be obtained. Since teachers are usually animated by a strong professional loyalty and *esprit du corps*, the situation has a tendency to make

them avoid teaching or expressing views which might alienate the class of persons upon whom the development of the institution most obviously depends. An insecure tenure of office and uncertain economic status operate in the same direction. The chief safeguards against these dangers are the increase of the scientific spirit of impartial inquiry and the growing solidarity of teachers and thinkers in different institutions. So far as the consensus of scientific equals is substituted for the irresponsible action of administrative superiors as the final court of appeal, there is little danger of either exploitation of personal opinions or of infringement upon that intellectual liberty which is the essence of university life.

**Germany.**—In the sense that the limitations under the uniform control of scholasticism and catholicism were so strong that attempts to go beyond them were rare, the German Universities of the Middle Ages enjoyed considerable *Lehrfreiheit*. Aside from these general ecclesiastical and scholastic limitations, there was no prescription as to what should be taught, the maxim being *quisquis præsunitur bonus*. The Reformation, however, brought with it a great change in the attitude toward education, and particularly to the universities. Both now came to be regarded as instruments of control. At the universities were educated the future clergy and state officials; hence certain religious tenets must be rigorously taught and observed there. The aim of each petty ruler now became to secure the control of a university in his state. Hence the foundation or reorganization of numerous universities in Germany during this period. Not only were new arrivals and candidates for academic offices questioned on doctrinal matters, but restrictions were imposed on the attendance of the members of a state at universities outside that state. Not only were the subjects which should be taught prescribed, but their extent and nature was limited. Thus at Wittenberg there was a provision for the teaching only of the Augsburg confession under penalty for breach. At Marburg the following provision was included in the Charter: "Whoso teaches contrary to the word of God, let him be accursed." Church attendance was insisted upon at most universities, and at Königsberg attendance at least at one theological lecture was prescribed for all members. Melancthon's activity in the founding or reconstitution of the universities was marked by the uniform regulations found in so many universities in Germany at that time. "Science" (including under that term theology, jurisprudence, medicine, language, and the liberal arts) was to be "taught according to the word of God." Denominational universities arose as bulwarks against heresy. Professors were appointed and paid by the states; the examination and graduation of students were under the supervision of the governments. Undoubtedly the Reforma-

tion checked the spread of the Humanistic tendencies, and in education, at any rate, introduced a reaction, which was not broken down for two centuries. At the end of the seventeenth century opposition to the scholastic and religious restrictions at the universities began to make itself felt. Christian Thomasius (*q.v.*) was compelled to leave Leipzig because he attacked the principles of the Court and insisted on using German in his lecture. Spener (*q.v.*) was driven from Leipzig and Wittenberg for his Pietistic tendencies. Francke (*q.v.*) in the same way incurred the opposition of the official theologians. These and others found safety under the protection of the Court of Brandenburg, which now sought to establish its importance through a state university founded on liberal principles. This led to the foundation of the University of Halle in 1694, to be open to members of all denominations. Here Thomasius lectured in German, Francke spread the principles of Pietism, and Christian Wolf (*q.v.*) broke down the scholastic philosophy by his pronounced rationalism, which found expression in his *Vernünftige Gedanken*. Gradually the sciences were secularized; natural law was made the basis of jurisprudence; the subjectivity of belief was insisted upon. In 1734 the University of Göttingen was founded entirely on the principles of academic freedom. Genuine scientific research was permitted and encouraged, and every faculty enjoyed a similar freedom. It was a sign of the times that, only thirty years after the expulsion of Thomasius, the University of Leipzig permitted Gottsched to lecture on Wolfian philosophy and German poetry. Since that period the German universities have enjoyed the freedom, which was then won, without disturbance. The strength of the universities was considerably increased at the beginning of the last century by the rise of the *Burschenschaften* (*q.v.*) The foundation of the University of Berlin and the appointment of Wilhelm von Humboldt (*q.v.*) were an embodiment of the traditions which had been established. The *Aufklärung* had its most numerous adherents in the universities. When the Revolution of 1848 took place, the King of Prussia, Frederick William II, and his supporters attributed it to the exaggerated worship of the cultivation of the mind instead of the heart due to the *Aufklärung*. Their attitude was well illustrated by the attacks and restrictions placed on the gymnasiums and normal schools. But the universities were now too strong and remained immune against any governmental interference. Not only have the universities grown in academic freedom, but politically they are the most democratic bodies in Germany. Several attempts, all of them ineffectual, have been made to limit this freedom, and when the Prussian ministry decided in a recent case that membership of the social-democratic party was sufficient reason for exclusion from the

position of a university lecturer, the whole of the faculty of the university concerned rose in opposition to this decision. The only restriction which can be exercised, is indirect through the method of appointment to the chairs and by the requirements for state examinations. Even in theology the government has refused to allow any limitations or control, which the church authorities are demanding. The most unrestricted members of the universities are the Privat Doctents (*q.v.*), who are not state officials, and are permitted to lecture by the faculty. "Science and the teaching of science are free" in the German universities, possibly more free than was the intention of those who framed the Prussian Constitution of 1850.

**England.** — The English universities of Oxford and Cambridge asserted their independence of Papal control at a very early period. The views expressed by William of Occam (*q.v.*) against the authority of the Pope gained a ready hearing at Oxford, and in 1368 the university obtained its independence from the Papal representative, the Bishop of Lincoln, in the election of the Chancellor. Cambridge similarly became independent of the Bishop of Ely in 1430. On the whole, however, the universities were the seats of orthodoxy, as was instanced by the persecution of Wyclif and the Lollards and the still earlier neglect of Roger Bacon. The political importance of the universities was emphasized during the Reformation, but they did not serve as easy tools of the monarchs in the same way as the German universities. Henry VIII found a considerable amount of independent thought on the divorce question, which he referred to Oxford and Cambridge, and only obtained a judgment which was satisfactory to him by the exclusion of members from convocation. The Reformation was introduced in the universities, not without a struggle, as was testified by the number of academic adherents to Catholicism when Mary came to the throne. The Edwardine Commission had had an important influence on the studies of the universities by abolishing the study of canon law. The result of the legislation of the sixteenth century was to introduce the imposition of tests on students, fellows, and heads of colleges at both universities. The ecclesiastical influence continued to increase in the next century, when Land imposed tests, insisted on attendance at university sermons, and reinforced the licensing of teachers by clerical authority. By the Caroline Statutes (1636) it became the duty of the Vice-Chancellor to safeguard the orthodoxy of the pulpit. The traditions established at this period continued until the middle of the last century and established the universities as instruments of the Anglican Church. Politically the effect was the same, as was illustrated by the Tory ascendancy at the universities during the eighteenth century, in spite of the interference with their liberties by James II,

who attempted to secure the selection of some Romanists to fellowships and masterships of colleges at Oxford and Cambridge. The effect of the imposition of religious tests and subscriptions was to exclude dissenters from the universities for nearly three centuries; there were tests on matriculation, on proceeding to degrees, on election to fellowships and headships of colleges. Under such circumstances the universities became close corporations, and academic freedom was recognized within the limits which they established. The effect of the tests was to lead to the establishment in 1825 of the University of London, followed a few years later by the northern colleges. In 1851 all oaths and declarations at matriculation and on taking the degrees of Bachelor of Arts, Law, or Medicine, were abolished at Oxford, and in 1856 at Cambridge for all degrees except in Divinity; further tests were removed in 1871, and since 1882 there are no tests for fellowships. At present there are no religious restrictions in any English universities, with the exception of those for professors of theology at Oxford and Cambridge. Otherwise academic freedom is complete throughout the country, especially since the newer universities were established as a protest against the restrictions of the older. The rule which holds at Oxford for professors, "He may lecture in such manner and form as he judges to be best for the instruction of students and the advancement of knowledge," has general validity. Such restrictions as are still found at the older universities are of a kind which prevent progress and adaptability to modern requirements, but are due to the peculiar nature of their constitutions, which retain for the universities the character of a close self-perpetuating corporation.

See CAMBRIDGE, UNIVERSITY OF; OXFORD, UNIVERSITY OF.

**France.** — In the university of Napoleon the faculties took the place of the old special schools, and were designed not for free scientific research, but for the preparation for and the conferment of degrees. They were entirely subordinated to the central authority, which regulated the use of their appropriations, the nature and subject of this instruction, nominated the professors and other teachers and employees. The syllabus of courses was submitted each year for the approval of the Minister.

The faculties at present still insist on the passing of examinations and prepare for certain examinations (licentiates, certificates, etc., or competitive tests (*agrégations*, inspectorates, etc.); but they have a very considerable, if not absolute, scientific and financial autonomy, since the transformation of the groups of faculties in universities. This change has been demanded ever since the ordinance of 1814, which proposed the establishment of several local universities, and was sketched in Guizot's (*q.v.*) plan for the organization of

large centers for study and outlined in the projects of V. Duruy (*q.v.*) and J. Simon (*q.v.*). Under the direction of M. Liard the change was realized in its broad lines by the decree of Minister Goblet (Dec. 28, 1885) and the laws of April 28, 1893, and July 10, 1896, which created "each faculty, then natural groups out of them, like living organizations with their own life and a soul, truly individual" (L. Liard). Established in this way, the French universities differ from those in England, which receive little from the State and can ask nothing from it, and much more from the German universities, which, even though electing their rectors with full liberty are still under the strict control of the State in the use of appropriations and the nomination of the professors. An attempt to secure this organization had been made at the time of the establishment by V. Duruy of the *École pratique des hautes Études*, in which the instructors were free to select the subjects of research or instruction.

The present situation is as follows: (1) The group of faculties in each capital of an academy is under the direction of the Council of the University nominated by the professors and presided over by the Rector, as the deputy of the Minister. The council is a civil person, implying the power to receive and acquire by way of gifts or legacies, or subsidies from towns, departments, or individuals, sums which with the state appropriations constitute the budget proper. (2) Each group, having itself become autonomous, is called a university, in which the different faculties can themselves decide on their courses, on condition that these offer a suitable preparation for the degrees or competitive examinations; can create or change some chairs; can introduce new studies to meet the needs of their district (*e.g.* local history, provincial dialects, local industries); and can deliberate on the use of their budget, etc. (3) Each university has full disciplinary power over its officers and students; and may present candidates to vacant chairs; the Dean may appoint persons for certain services.

In short in the present system, "instead of compelling the faculties to put its ideas into operation, the central administration assumed the task of putting into practice those which come from the faculties or have their approval" (L. Liard). The universities thus find themselves situated between the influence of the state administration and political and social influences of their own local center and their conception of their scientific function. This conception they realize in proportion to the scientific standing and personality of their professors. J. P.

**United States.** — The problems connected with the right of academic freedom in the American colleges and universities divide chronologically into three quite well defined groups or periods.

The first of these periods includes the

seventeenth and eighteenth century, wherein the authority threatening this freedom is ecclesiastical, and the interests supposedly threatened are sectarian. The first president of Harvard afforded the earliest instance. President Dunster was "persuaded to resign" in 1654, after fourteen years of most valuable service, because of anti-paedobaptist beliefs. The second president, Chauncey, had suffered suspension from the ministry and imprisonment in England for exercising the right of free speech as a minister, but his orthodoxy was unquestioned in New England, especially in the doctrines in which Dunster was weak; "it being his judgment not only to admit infants to baptism, but to wash or dip them all over." The next difficulty in this respect at Harvard was in the early eighteenth century, when there was a prolonged struggle for control between the orthodox Congregational party and the aristocratic Church of England element, holding more tolerant religious views. While numerous restrictive acts were in the nature of limitations of freedom of belief and of teaching, yet such acts were but incidental to profound social and religious struggles. The early years at Yale also present instances of arbitrary restriction of the liberty of belief and of teaching. Yale had been but three years at its permanent site when trouble of this character arose with the first New Haven president. The breach occurred over so trivial a matter as the President's crying with raised hands at the close of the commencement services, "Let all the people say amen." This, however, presaged President Cutler's fall from office and his apostasy to episcopacy. Theological tests for all faculty members then were adopted, which remained until the nineteenth century. While students were at times expelled for religious indiscretions, such as attending services at churches other than the orthodox one, or petitioning to use Locke's *Essay on Toleration*, the test preserved the faculty from such infection. Most of the colonial colleges afford similar illustrations. The prolonged struggle at William and Mary, led by Thomas Jefferson, was a revolt against this restriction by ecclesiastical authority. Early in the nineteenth century, Jefferson gave up the attempt to free William and Mary from such control, and turned his attention to the founding of a new institution, — a state university, which, however, did not eventuate until the first quarter of the century was rounding out.

It will be noted that the restriction in nearly every instance was upon the freedom of belief in theological dogmas or practices by those in academic authority. Before the close of the eighteenth century Harvard had made long strides towards throwing off this incubus. At Yale, after a prolonged struggle involving the right of the student as well as of the teacher to hold religious beliefs heterodox to the authorities, the state government succeeded in forcing

*ex officio* representation on the board of trustees and a more liberal attitude regarding religious beliefs. Somewhat later the same difficulty was settled at Princeton by the organization of a theological seminary distinct from the college (1812).

The second period into which higher education in America may be divided, with respect to these problems, includes in a general way most of the nineteenth century. Instances involving infringement of academic freedom now arise chiefly out of the subject matter taught or ideas advocated, which involve a digression from religious views common to all Christian sects. Attempts to prevent such digressions now give rise to direct restrictions upon the liberty to teach freely the principles or data of a novel subject. Such cases arose immediately after the Revolution in connection with the French language and literature. These were supposed to be full of heretical suggestion, chiefly, no doubt, because many of the early teachers were "free thinkers." At Harvard in 1780 French was offered to those who obtained consent of parents or guardians. Eight years later a course on natural history was opened on the same terms. Thus was inaugurated the suspect period in science, which was to continue for almost a century.

Later, in the nineteenth century, novel geological and astronomical ideas occasioned a more eminent danger. But it was with the general formulation of the evolutionary theory by Spencer and Darwin that conditions became acute. The colleges of the nineteenth century were mostly denominational. Harvard's apostasy from Congregationalism, the Dartmouth College decision which protected religious bodies in the control of institutions founded by them and chartered by legislature, the failure of Jefferson's long struggle over William and Mary, and the numerous foundations of state universities, gave an unprecedented impetus to the founding of institutions of learning, especially in the more newly settled states. These were avowedly denominational in control and character; and while few were sectarian in teaching, all emphasized very strongly the religious character and importance of education. As such institutions attempted to keep abreast of rapidly advancing formulation of scientific principles, numerous instances arose of conflict between the right of an instructor to teach views for the time being held heterodox to many denominations or to Christian bodies in general. Hardly a college of the several hundred now existing but what furnished one or more illustrations of this situation. However, many influences have been at work to make the acceptance of the scientific views, heterodox to the middle nineteenth century, a matter of convention now; to adjust those views to religious conceptions acceptable to the present generation; and also to weaken the religious or at least denominational affiliation of many

of the colleges. Instances of loss of professional position because of such views probably occur yet; but they are rare, and do not entail the hardship upon the offending instructor they once did. So much of the injury resulting is to the offending institution that the offense is scarcely to be noted as one against academic freedom.

But within the present generation, a new era has been entered, and an entirely new kind of academic danger has arisen, through restriction of freedom of teaching. Problems of this character now arising relate to economic or social doctrine. The restriction arises chiefly because the control of our higher institutions of learning has passed to representatives of the secular as opposed to the ecclesiastical world. As one of the most serious forms of the "commercializing" of education and of culture, this situation is all the more dangerous because often not recognized by those immediately responsible for the violation of a fundamental social right, or even by those through whom the restriction arises. The situation is due partly to the enormous expansion of philanthropic gifts to education, partly to the participation of successful business men in collegiate control, — a feature which has been largely responsible for the progressive character of American education. — and partly the recent emergence of a vast number of social problems of fundamental human interest and importance. The most subtle and most common form in which this academic danger exists is where an institution has the friendship and patronage of a liberal donor, whose beliefs and prejudices must be respected even to the extent of avoiding consideration of certain subjects, the severance or termination of relations with certain instructors, or even the presentation of specific views on given subjects held by the patron. The administrative authorities of many educational institutions at the present time confess this as a real danger. It is less the limitation on academic freedom arising from gifts already made, than the restriction arising from desire to avoid offense where greater favors are desired and anticipated. The present generation has witnessed a number of instances where the favor of a living benefactor has been more fraught with danger than the traditional "dead hand." In order to avoid such contingencies one of the most generous of such patrons has wisely indicated to the favored institution that he has made his last gift, and has severed all relations with the institutions which he founded. The cases of violation of the right of free teaching, however, are not by any means confined to institutions having a special patron, but occur in all types of institutions, — one of the most flagrant of recent cases being in a state university.

During the past two decades a number of notable instances have occurred of the severing of academic relations because of the eco-

nomie or social views held and doctrines taught by the instructor involved. In one of these instances, the president of an old and honored New England university was concerned. The monetary problem, state control of railways and of other services, municipal control of such services, public concessions of questionable character, or even more general socialistic teachings, have been the occasion for the half dozen more prominent of these instances. It is but just to say that in almost every case there have been involved factors other than the orthodoxy of the economic doctrines involved. Methods of propaganda, traits of personality, local factional influences have entered into almost every case, so that justice cannot decide with precision. For the present it is not overt cases of this character which present the most serious danger to the right of free teaching and investigation, but the more subtle types indicated above. A few cases arising out of political partisan bias form a class by themselves; but such instances are rare, and are not apt to recur except in marked isolation. For related topics see LITERARY CENSORSHIP; and under COLLEGES, AMERICAN, the section on Administration of the Curriculum, for discussion of freedom of study.

**FREEDOM OF PRESS.** — See LITERARY CENSORSHIP.

**FREEDOM OF PUBLICATION.** — See LITERARY CENSORSHIP.

**FREEDOM OF WILL.** — In certain of its aspects, the problem of freedom of will has become so encumbered with the refuse and

débris of all kinds of other matters as to be best "solved" by letting alone. Some of these extraneous affairs are the divine government of the world, and the accompanying questions of foreknowledge and foreordination; the notions of cosmic fate or necessity, or, in mitigated form, the fixed law and physical causation; the legal and forensic questions of guilt, liability, and punishment, etc. Moreover, the psychological analysis is hampered by diverse and unsettled notions as to the nature of the self, and the nature of volition itself, especially in relation to emotion and reflection. Fortunately none of these difficulties seriously affect educational questions, while in those concrete matters with which education is concerned there is a general consensus of belief.

1. Freedom of will in the sense of motiveless choice is, even if it exists, of no importance for education, which is concerned with the formation of a character interested in ends that are valuable, and interested in a way that makes these ends stable and effective motives. Or, we can go farther, and say that such freedom, even if it exists, is of negative value to the educator; that is, it introduces a factor of arbitrariness, of caprice, of whimsical unaccountableness, that would be such an undesirable element of character that one of the aims of education would be to counteract it. The supposition that unmotivated choice would be of any positive worth is due to a false conception of motive; that is, to regarding it as a force which acts from without upon the self, as if the latter were passive or idle until externally appealed to. Since, however, the self is active on its own account (see EXPERIENCE; FUNCTION); a motive has its origin and residence within the self, so that in acting in accord with motive it may still be expressing its own nature.

2. Plasticity, tendency to variation, to growth, to readjustment of habit, are also native to the self. This covers a large part of the practical meaning of "free will," viz. power to reform, to develop, to alter unfavorable tendencies, and to take on new and better habits. Absence of freedom suggests a rigid domination from without which is fatal to growth and reconstruction from within; while, as a matter of fact, it is only in cases so extreme as to be pathological that initiative and plasticity cease.

3. Preference, selective activity in a specific direction, is also a concrete trait of human action. It has been said that the chief defect of both the conventional upholders and opponents of freedom is that they try to get behind the fact of preference; the opponents, by denying it or reducing it to an illusion; the upholders, by regarding it not as a self-sufficing fact, but something to be accounted for by reference to a faculty which is its cause. Once recognize that all organic activity is partial, preferential, interested in some special direc-

tion or toward some end, and we have included a significant element of freedom, practically unorderd.

4. Reflection presents and weighs alternatives. A thinking being is free in a sense in which no unthinking being could be free, even if fully endowed with "free will." For a reflecting agent can present to himself the consequences of a proposed act; he does not have to wait till the consequences are externally and irretrievably produced to see whether they are desirable or undesirable. If on reflection, the consequences are seen to be adverse, the proposed line of action, if dropped for preference or the bent of disposition, is shifted to some other alternative, which is then weighed. Just in the degree in which one is gifted with the habit of reflection, in that degree he is capable of acting in the light for a foreseen future instead of being pushed from behind by sheer instinct or habit.

With respect to freedom, then, the task of the educator is threefold. First, to keep alive plasticity, initiative, capacity to vary; to prevent induration and fixation in fossilized automatic habits. Even a thoroughly good habit needs to be kept flexible, so that it may be adapted, when the need arises, to circumstances not previously experienced even by way of anticipation. Secondly, to confirm preferences; to build up and strengthen positive and constructive interests in specific directions. Nothing is more fatal practically than the growth of a spirit of indifference, of boredom, or of miscellaneous and easily diverted responsiveness. Thirdly, to make preferences *reasonable*; that is to say, to develop in individuals the habit of forecasting the consequences of acting upon a given preferential tendency, of comparing one set of results with another, and by these means enlightening preference as its own deeper and more abiding nature. Capacity transforms habit when required. Steady and specific interests, foresight, and deliberation, — given these factors of character, and purely speculative difficulties in the concept of freedom may be left serenely alone.

FREEMAN, ALICE. — See PALMER, ALICE FREEMAN.

FREIBERG, SAXONY, ROYAL SCHOOL OF MINES. — Established 1765 and opened in 1766. Freiberg has the distinction of being the first, and, for a time, the only technical university in the world. It was the pioneer

in the application of scientific research to practical problems. From a very early period in its history the relation between theory and practice was not lost sight of, and the modern method of technical instruction through lectures, discussions, laboratory practice, and a considerable amount of field work was perfected here. Its early reputation is connected with the mineralogist and geologist, Abraham Gottlob Werner, who taught there from 1775. As reorganized in 1871, the institution was placed under the Minister of Finance. Students from nine-year secondary schools are admitted. The course of study for a diploma extends over four years. Students from Freiberg may obtain the doctorate in engineering at the Dresden Technical High School on the presentation and defense of a thesis. In 1910 the student enrollment was 480. The town is the center of important smelting and mining industries in the Erzgebirge. The gymnasium at Freiberg was established in 1515.

**FREIBURG IN BREISGAU, BADEN, THE GRAND DUCAL ALBERT-LUDWIG UNIVERSITY OF.**—Established by Archduke Albert of Austria in 1456, and one of the oldest universities in Germany. It attained great prominence in the days of humanism, being the center of learning for the Upper Rhine region. In 1620 the Jesuits assumed charge of the instruction in theology and philosophy, and, owing to the Thirty Years' War, a period of decline was ushered in, which continued for almost a century and a half. The Austrian government then took steps to place the institution on a more solid foundation by strengthening its teaching staff, and these efforts were nobly seconded by the Elector (later Grand Duke) Charles Frederick of Baden, into whose hands the Breisgau, formerly a hereditary possession of the House of Austria, had passed by the Peace of Pressburg (1806). The maintenance of two universities, Heidelberg and Freiburg, by a country as small as Baden furnished a problem of no mean magnitude; and on more than one occasion there was grave danger of the absorption of the younger of the two universities by the older and more renowned; but Freiburg has prospered and expanded, especially of late. The number of its summer students has grown from 225 in 1870 to about 3000 in 1910, while it ranks eighth in size to-day in the number of winter students, its beautiful location on the edge of the Black Forest being to a certain extent responsible for its popularity. The total attendance at the winter semester of 1909-1910 was 2305 (133 women), including 138 auditors (47 women), the matriculated students being distributed as

follows: theology, 218; law, 415; medicine, 713; and philosophy 816; the medical school being exceeded in size only by those of Munich, Berlin, and Leipzig. In contradistinction to Heidelberg, Freiburg's theological faculty is Catholic, the Catholic theologians having been transferred from Heidelberg to Freiburg in 1817. The library contains about 300,000 volumes and 700 Mss., and the annual expenditures for the university amount to about \$250,000. Among renowned teachers may be mentioned Zasius in jurisprudence, the famous preacher, Geiler von Kaisersberg, and Luther's opponent, Eck; among later ones Jacobi, the poet, and the historian Heinrich von Treitschke. **FREIBURG, SWITZERLAND, UNIVERSITY OF.**—An institution of recent origin, having been established in 1889. It consists of four faculties, viz. theology, law, philosophy, and pure science. The cantonal and university library contains 200,000 volumes and over 500 Mss. Closely associated with the university are the Historical Museum, the National History Museum, and the State Archives of Freiburg (almost 17,000 parchment documents). Lectures are given in the German, French, and Latin languages. During the winter semester of 1909-1910 there were 724 students in attendance, including 120 auditors. They were distributed by faculties as follows: theology, 235; law, 124; philosophy and pure science, 245. It is the smallest of the Swiss universities, with the exception of Neuchâtel. R. T.

**FRELINGHUYSEN, THEODORE** (1787-1861).—Statesman and educator; born at Millstone, N.J., March 28, 1787. He was educated at the grammar school connected with Queen's College (now Rutgers), and was graduated at Princeton in the class of 1804. He took up the profession of law, but devoted considerable time to educational movements, and was active in the American Lyceum Association (*q.v.*). He was president of New York University from 1839 to 1850, and of Rutgers College from 1850 to 1861. He was the author of numerous pamphlets on the value of public education. He died at New Brunswick, N.J., April 12, 1861. W. S. M.

**FRENCH INFLUENCE IN AMERICAN EDUCATION.**—Through the greater part of the seventeenth and eighteenth centuries educational progress in the colonies had gone hand in hand with that in England, and all non-English influences—except that of the continental Reformers, especially Calvin—had been very slight. Such elements in the colonial population as the Dutch of New York and the Germans of Pennsylvania had no inconsiderable influence on the education of those states. And the character and intelligence of the French Huguenots formed even a greater power throughout New England, New York, Virginia, and the Carolinas. It has been said (Baird, *History of Religion in America*, p. 158) that “next to the English Puritans and the Scottish Presbyterians we must rank the exiled Huguenots . . . as having done most to form the religious character of the United States”; and education went hand in hand with religion. So, too, the influence of individual Huguenots and descendants of Huguenots, men like Benezet, the Huguenot Quaker who founded a school for negroes in Philadelphia, like Bowdoin, Faneuil, Laurens, and a little later Audubon, is not to be ignored.

But a new element entered into the whole situation when there came not only the break with England, but the alliance with France. With the treaty of 1778 begins a period in which we might reasonably look for a definite and specific French influence. Spiritual influence is of necessity subtle, intangible, difficult to determine. But a definite application of French ideas may be noted as demonstrable or probable in (1) the founding of the American Academy of Arts and Sciences in Boston in 1780, and the Academy of Sciences and Fine Arts in Richmond; (2) the founding of the state universities of Georgia (1784-1785), New York (1784-1787), and Michigan (1817-1824); (3) the educational influence and labors of Thomas Jefferson in Virginia.

1. Benjamin Franklin (*q.v.*) had founded in 1743, and on a firmer basis in 1769, the American Philosophical Society held in Philadelphia for the Promotion of Knowledge. John Adams, as he himself tells (*Works*, ed. C. F. Adams, Vol. IV, p. 257 *sq.*), heard the Philadelphia Society praised on every hand by the scholars whom he met in Paris in 1780, and the idea was there suggested to him that a similar society should be formed in Boston. The project took root. But Boston being full just then of hostility to things English and of friendliness to things French, the founders of the new institution called it an Academy, not a Society, stating it as their intention “to give it the air of France rather than that of England, and to follow the Royal Academy rather than the Royal Society.” This feeling disappeared in time, naturally; but its traces survived in the name and in the custom of

issuing the transactions of the Society as *Memoirs*.

The Academy of Sciences and Fine Arts in Richmond was founded by the Chevalier Quesnay de Beaurepaire, a French volunteer in the American army and a grandson of the physiocrat. He stated his aim to be that “of connecting the United States with my fatherland by new motives of gratitude, of conformity in taste, and of more close communications between the individuals of the two countries.” Its specific purpose was to foster the arts and sciences after the general model of the French Academy and to establish advanced instruction in foreign languages, mathematics, design, architecture, painting, sculpture, and the sciences (not Latin or Greek), the professors to be selected by a committee of correspondence in Paris. The whole project was endorsed by Jefferson and by many others on both sides of the Atlantic,—Condorcet, Malesherbes, La Fayette, and Lavoisier among others,—and a considerable sum of money was subscribed in France as well as in America. The erection of a building was begun in 1786, and carried to completion. But the project depended so largely on France that it was killed by the Revolution, and the building was used for other purposes. In the words of a French writer, “a theatre replaced the Academy, and the German spirit supplanted the French in American Education.”

2. The first organization of the University of the State of New York as a state system of education was made in 1784, with Columbia College as its dominating element. Three years later the charter was modified, lessening the power of Columbia and emphasizing more strongly the ideas of state representation and state supervision. The University of Georgia was founded by state enactment February, 1784, amended in January, 1785, the fourteenth section of the bill declaring that “all public schools instituted or to be supported by funds or public money in this state shall be considered as parts or members of the University and shall be under the foregoing directions and regulations.” (See UNIVERSITIES, STATE.)

Many details of these measures were peculiar to the states concerned and dictated by local conditions and needs. But the idea as a whole was quite new in America and unknown in England; whereas it was familiar in France, at any rate as an ideal, and it is not unlikely that it came to America directly from the literary and political circles of Paris. There had been a marked tendency toward the centralization of education in France ever since the sixteenth century (Gobron, *Législation et Jurisprudence de l'Enseignement*, Paris, 1896, p. 18 *sqq.*), but like the equally marked centralizing tendency in government, it had been hindered by innumerable local and ecclesiastical privileges, and had never been completed. The eighteenth century brought an

increase of abuses, and confusion that aroused widespread protest, and the first important step towards reform—the expulsion of the Jesuits in 1762—threw the already tangled and ineffective educational system of the country into a confusion ten times worse. The philosophers on the one hand, and the enemies of the Jesuits in the Parliaments on the other, were alike stimulated by the needs of the situation to a series of efforts toward the reducing of the chaos to order. One of the first and best treatises called forth by the problem was that of La Chalotais, Procureur-général of the Parliament of Rennes, with the significant title, *Essai d'Éducation nationale*, but though La Chalotais maintained that the State should be responsible for and should control education, he did not attempt to outline an actual administrative scheme. This was done, however, along similar lines, by Guyton de Morveau at Dijon, and notably by Rolland d'Erceville, president of the Parliament of Paris, in his *Compte Rendu* of 1768, published in 1783 under the title *Compte Rendu, ou Plan d'Éducation et de Correspondence des Universités et des Collèges*. In the meantime Diderot, in 1776, had drawn up his famous *Plan d'une Université* for Catherine II. This remained in manuscript, it is true, until Guizot published extracts from it in 1813–1814; but it was certainly known to Naigeon in 1784–1795, and to Henri Meister, the secretary of Grimm, in 1786. At any rate, the result of the whole movement in France was seen in the successive projects of Mirabeau, Talleyrand, Condorcet (*qq.v.*) and their successors, and finally in Napoleon's university in 1808. The organization of the University of Georgia and that of New York in 1785 and 1784–1787 respectively fit in exactly with the evolution of education in France. As an actualized fact, these two universities antedate the University of France by more than twenty years, but they are the product of the same intellectual evolution.

3. The evolution in France of a state system of education crowned by a national university was a living thing to Thomas Jefferson, as to no other American of his time. If he gave but half-hearted support to Washington's plan of a national university at the capital, it was because he believed characteristically that such a project was the affair of each state; though in 1794, moved by the greatness of the opportunity, he did urge the transfer of the University of Geneva to the United States *en bloc*. In Virginia he identified himself with three educational movements: (1) a graded system of state education topped and controlled by the College of William and Mary; (2) a reform of William and Mary along French lines by the introduction of modern studies; (3) the establishment of a state university. The plan of state education was proposed in 1779 and partly carried out

in 1796, fatally spoiled as far as the original intention was concerned by leaving its execution optional to local authorities and by the omission of the crown of the system—the university. The whole scheme is strikingly similar in essential principles to those mapped out by Rolland in 1768–1783, by Talleyrand in 1791, and by Condorcet in 1792. It is, indeed, decidedly more analogous to the French plans than was the University of the State of New York. Talleyrand's system, for instance,—*l'école cantonal, l'école d'arrondissement, les écoles spéciales* (professional), and *l'institut national*,—is practically an exact version in French of Jefferson's scheme of 1779 or the revised scheme suggested in his letter of September, 1814, to Peter Carr. The analogy is so close, the plan so foreign to anything hitherto planned in America or England, and Jefferson's French proclivities so clear, that a definitely French influence may be inferred with practical certainty.

The reform of William and Mary Jefferson regarded as an essential element in his proposed state system. As a visitor of the college in 1779 he was responsible for several changes, involving the abolition of the professorships of divinity and oriental languages, and the substitution of professorships in law and police, anatomy, medicine, chemistry, and modern languages; the laws of nature and nations, fine arts, and natural history were also added to the subjects already taught. "These propositions," comments Professor Adams, "represent the first current of modern ideas, which began in 1779, at Williamsburg, to flow into American academic life." Their source may be seen in a glance at any one of the many proposals for university reform made in France, from Rolland to Napoleon. (See COLLEGES, AMERICAN, HISTORY OF.)

The establishment of the University of Virginia was Jefferson's last and perhaps greatest educational achievement. Reluctantly convinced that William and Mary would never adopt the large and living educational point of view which he regarded as essential in an ideal state university, he seized on the movement for the founding of an academy at Charlottesville in 1814 as an opportunity to work for the establishment of a new institution for higher learning. The academy became Central College—a name borrowed from the familiar *École Centrale* of France—and Central College, through the unceasing efforts of Jefferson and his devoted fellow worker, Joseph Cabell, became the University of Virginia by legislative enactment in January, 1818. In the new university were embodied the ripest fruits of Jefferson's observation and experience in Europe. In its aim of making worthy citizens, its reliance on state support, its freedom from church influence, its subordination of the classics to the modern languages, political science, and the natural sciences, it reflected

the whole current of French educational theory and practice. Its division into schools rather than into the ancient four faculties (arts, theology, law, medicine) had been clearly outlined in Diderot's *Plan d'un Université* (1776) and in Dupont de Nemours' work *Sur l'Éducation nationale dans les États-Unis* (1800). "The idea of distinct schools of art and science which is so prominent a characteristic of the University of Virginia to-day," says Professor Herbert Adams, "is the enduring product of Jefferson's observation of the schools of Paris, and of his association and correspondence with their representative men."

A further channel of French influence on American education was the introduction of the French language and literature into college and academy curricula. The finishing schools, especially those for girls, of the latter half of the eighteenth century frequently advertised the teaching of French. Here, however, it was classed with music, dancing, and embroidery, as a "polite accomplishment." During this period and the early nineteenth century, French was introduced into some of the more advanced of the academies on a somewhat higher plan. Its introduction into the college curriculum during the same period had, however, more profound educational significance.

Instruction in French had been allowed at Harvard as early as 1735. But the instructor, "who had been employed under the authority of the president and tutors as an instructor in French," was accused of "disseminating certain dangerous errors in college," and the experiment was short-lived. In 1769 it was voted that a certain Mr. Curtis, "professing himself to be of the protestant religion," be allowed to teach French to such scholars "whose parents by writing under their own hands shall signify their desire for that purpose to the tutors, except in the hours appointed for academical studies and exercises." With the Revolution opposition to things French became less pronounced, and was replaced in many academic centers by enthusiasm. The College of William and Mary established a chair of modern languages in 1774; and Columbia the first chair in French in 1784. The first chair in French at Harvard was founded in 1815, by which time several other colleges had made similar establishments.

The introduction of the study of French was associated with the period in American college history, from 1770 to the second decade in the nineteenth century, which was marked by the growing freedom and license of the student body, by decline of faculty control, by the overthrow of the strict ecclesiastical dominance, and by the introduction of the study of the sciences. The early part of this period, the years of and immediately following the Revolution, was characterized by license in conduct, and extreme freedom of thought and infidelity among the students. To a certain extent this was associated in the popular

mind with the French influence. Consequently came this opposition, cited above, to the study of French. It is impossible to say now to what extent such influence did or could come from the study of the language of the French literature, but it certainly formed an influence by which ideas more tolerant to broader views of life were brought in at that time. It was an important means for making known the French ideas of that most important epoch.

Since the early part of the nineteenth century the influence of French educational ideas and practices on America has been very slight; and such as has been exerted came indirectly through Swiss or German channels, and was of a vague and indefinite cultural character, which has little connection with organized education. See, however, FRANÇAIS, ALLIANCE. C. F. L. and P. M.

**FRENCH INFLUENCE IN ENGLISH EDUCATION.**—

The ecclesiastical and political connection between France and England during the Middle Ages constantly enriched the scholarship and education of both countries by the influence of men of learning and administrative ability. This reciprocal influence is illustrated by the work of Alcuin of York (c. 735-804) and Alfred (849-901). The former, from 782 to 790, was master of the Palace School, established by Charles the Great, of whose educational policy he was the chief instrument. "In the morning of his life," he wrote, "he sowed in Britain; and now, in the evening of that life, he ceased not to sow in France." The educational plans of Charles the Great served in turn as a model for those of the English king, Alfred, the first great organizer of education in England.

From French centers of learning there were drawn many of the organizers of English education. Thus Oswald, Archbishop of York (d. 992), having himself been educated at Fleury on the Loire, invited the Abbot of Fleury to become instructor to the monks at the abbey founded by the archbishop at Ramsey. The Norman Conquest strengthened the connection between France and England, and from the Norman Abbey of Bec, famous for its educational activities, came Lanfranc, consecrated as Archbishop of Canterbury in 1070, and

Anselm, consecrated as his successor in 1093. Both of these archbishops maintained the cause of learning in England, and by their policy strengthened the control of the Church in English education.

The great school of Chartres (*q.v.*) attracted many students from Britain, *e.g.* John of Salisbury (d. 1180) and Adelard of Bath (*qq.v.*). But the University of Paris, described by Alexander Neckam as *paradisus deliciarum*, was the great lodestone of British students and the dominant influence in the creation of the English universities. It is probable that the older Oxford schools rose to the position of a *studium generale* through a migration of students from the University of Paris about 1167, and the great dispersion of the masters and scholars from Paris in 1229 may have been the chief factor in the early development of the University of Cambridge. One of the four nations into which the Faculty of Arts was divided at the University of Paris bore the name of the English; and, though the latter shared their membership with Germans and other students from Northern Europe, the fact that they gave their name to it shows their numerical importance in this division of university life. Edmund Rich of Abingdon, Roger Bacon, and William of Ockham were students at Paris as well as at Oxford. The intellectual and personal ties between the two universities were very close, especially in the thirteenth century. Oxford recalled Paris in constitution and in customs. It may be said that France gave England much of the form of its ancient university institutions, and inspired Englishmen with the love of scholastic philosophy in which they excelled.

In the English grammar schools French influence was strong down to the middle of the fourteenth century. From the Norman Conquest the pupils were compelled to "leave their own language and to construe their lessons in French." John de Trevisa noted, however, in 1385 that this custom, which had been prevalent down to the first appearance of the Black Death in 1349, had already changed, so that "in all the Grammar Schools in England, children leave French and construe and learn in English." (See ANGLO-NORMAN DIALECT.) This great change may have been due to the mortality of the French priests at the time of the Black Death (*q.v.*) or to their departure to escape its infection. The break in educational tradition thus caused by the plague opened the way for the general use of the mother tongue in the English grammar schools. In methods of teaching Latin, however, the old influences held their own. One of the two Latin grammars most used in medieval English schools was written by Alexander of Ville Dieu (*q.v.*) in Normandy, who kept a school in Paris and wrote in 1209 his *Doctrinale Puerorum*, a grammar in Latin verse. Throughout the Middle Ages, indeed, the English education was

in great measure assimilated to continental models, in forming which French culture bore a leading part.

Passing over the period of the Renaissance, during which French influence in English education was intermixed with Italian, we come to the age of Louis XIV, when French standards again determined the course of instruction and training for boys in many families belonging to the wealthier classes of English society. This wave of French influence culminated in Locke's *Thoughts concerning Education*, published in 1693. In Locke there are marked traces of the influence of Montaigne, of Descartes, and of the Gentlemen of Port Royal. The schoolbooks prepared by the Port-Royalists were used in England, and became a model for the writers of Latin and Greek grammars for use in English schools. The strength of French influence upon English ideals of education during the first half of the eighteenth century is shown in Lord Chesterfield's *Letters to his Son*. "A Frenchman," he writes, "who with a fund of virtue, learning, and good sense has the manners and good-breeding of his country, is the perfection of human nature. This perfection you may arrive at, if you please, and I hope you will do so." To behave in all companies as a cultivated French gentleman would behave was the standard of manners to which he most desired that his son should attain. Through the writings of Rollin, the inheritor of the traditions of Port Royal, the educational influence of France percolated very widely through English teaching in the middle of the eighteenth century. The wider curriculum of study which French writers made popular attracted Joseph Priestley (*q.v.*), who, in an *Essay on a Course of Liberal Education for Civil and Active Life*, published in 1765, advocated a new ideal of liberal culture in the education of the English middle classes, then rapidly rising in social influence and political power.

The writings of Fénelon and of Madame de Lambert (1647-1733) greatly influenced English ideas about the education of girls. No English book did more to raise the moral standards of girls' education than the *Serious Call*, published in 1728 by William Law, himself a careful student of Fénelon.

The writers in the French *Encyclopédie* influenced the thought of Adam Smith, whose references to public education in the *Wealth of Nations* (Book V, Chapter I, Article II), published in 1776, greatly affected English policy in regard to educational questions. An essay on endowments (*q.v.*), written by Turgot in 1756, seems to have made a deep impression upon the mind of Adam Smith. In this paper Turgot endeavored to demonstrate the obstructive effects of educational and other endowments in national life. In the *Wealth of Nations* Adam Smith argued that the endowments of schools and colleges had diminished

the necessity of application in the teachers, and had prolonged acceptance of exploded and antiquated opinions. His practical inference was that in secondary and higher education voluntary effort and the free play of supply and demand would always accomplish more than endowed institutions, the existence of which hampered the growth of independent initiative. At the same time he was forced to admit that the State should impose upon "the whole body of the people the necessity of acquiring the most essential parts of education." But in thus acknowledging the necessity of some measure of governmental intervention, Adam Smith's scheme fell far short of the later educational plan of Turgot, contained in the latter's memorial to the King *Sur les Municipalités*, written in 1775. In fact, Adam Smith reflects the first phase of French revolutionary influence in English educational thought. He shared with the French Radicals a distrust of ecclesiastical control in public education and a desire to sweep away the power of ancient educational endowments, on the ground that these were mainly connected with clerical effort. He also perceived that, in place of the Church, the State must enforce at least a minimum of educational discipline throughout the nation. But here he stopped, while his French contemporaries were swiftly carried forward to the point at which they advocated a stringent form of state control over all grades of schools and colleges. From about 1760 to 1810, French speculation had a double influence upon English educational opinion. One side of its influence was liberative and antagonistic to old conventions. It encouraged a return to nature in educational method. It deepened the dislike of old endowments and drew attention to their torpor, inelasticity, and failure in public duty. This side of the influence of French revolutionary thought, strongest through Rousseau, showed itself in Mary Wollstonecraft's *Vindication of the Rights of Women* (see GODWIN, MARY WOLLSTONECRAFT), with its argument for coeducation both in elementary and secondary schools; in the writings of Richard Lovell Edgeworth (*q.v.*), and his daughter, Maria Edgeworth (*q.v.*), and in the educational experiments of Thomas Day (*q.v.*). The other and conflicting tendency of French revolutionary thought in education was toward some more stringent form of public control over all grades of schools. This influence showed itself in a rudimentary form in Adam Smith's *Wealth of Nations*, but more conspicuously and with logical completeness in Robert Owen's *New View of Society* (1816). These two currents of thought had a double effect upon the more conservative side of English education. They produced a movement for self-reform within the older endowed institutions; and at the same time they made public opinion reluctant to sanction any great extension of educational opportunities, for fear lest

the sudden increase of book knowledge should precipitate violent political change. The reforms at Oxford in the earliest years of the nineteenth century, the increased activity of many of the old endowed secondary schools, and the energetic efforts of the Church of England and other religious bodies to grapple with the educational destitution of the masses of the people, a work which had the hearty support of Wordsworth and Coleridge, were illustrations of the first result. The rejection of Mr. Whitbread's Bill for Elementary Education in 1807, which, if carried at the time, would have anticipated some of the great reforms of 1870, showed how potent were the fears to which French revolutionary thought and action had given rise among the more conservative classes of English society.

French influence in English education during the century 1810-1910 falls under three main heads, (1) philosophical, (2) political, (3) administrative.

1. In the domain of direct philosophical influences, the names of three French thinkers are of preëminent significance in their relation to English educational thought, -- Helvétius, Saint-Simon, and Auguste Comte. Helvétius (*q.v.*) had a strong posthumous influence upon Robert Owen, Jeremy Bentham, and George Combe (*qq.v.*). The realism of his political thought, the emphasis which he placed upon personal interest as the primary motive of action, his belief in the omnipotency of education, and his conviction that there must be a close bond between the life of the individual and that of the community, showed themselves in English thought (*a*) in a growing disposition to recognize the claim of every individual to equal educational opportunity, (*b*) in that individualistic utilitarianism which took rather a matter-of-fact and prosaic view of the course of instruction, (*c*) in impatience with whatever obstructed the spread of this new educational ideal, and (*d*) in an undercurrent of collectivist thought in matters of school organization. To the influence of Helvétius that of Saint-Simon (1760-1825) and his followers was a corrective. It showed itself especially in the change of tone in the writings of John Stuart Mill (*q.v.*) from 1830 onwards; in the gradual weakening of the spirit of anti-governmental *laissez-faire* which had affected much of English liberalism; in a freshly kindled passion of interest in the poor and pity for their condition; and, not least, in a strong conviction that women should enjoy social and educational opportunities equal to those of men. The influence of Comte (*q.v.*) and of Positivism showed itself mainly in a growing belief in science as the chief factor in education. It also weakened the more fanatical kind of anti-clericalism by emphasizing the need for a spiritual authority in national education.

2. The political influence of French thought upon English educational affairs centers chiefly

round three dates: 1833, when Guizot organized French elementary education; 1850, when the *Loi Falloux* recognized two types of elementary school, viz. public schools maintained by the communes and private ones maintained by individuals or by religious associations; and 1881, when Jules Ferry (*q.v.*) abolished school fees. Each of these three measures had a direct influence upon English education. Guizot's act of 1833 helped in convincing English statesmen that the government must take a more active part in superintending the work of elementary schools, and thus helped in securing the first vote for training colleges (the name of which, "normal school," was taken from France) in 1835, and the establishment of the Committee of Council on Education, the germ of the Education Department, in 1839. The *Loi Falloux* of 1850 probably suggested (not to W. E. Forster, but to those whose ideas influenced his administrative proposals) the plan of the dual system of board schools and voluntary schools, each recognized and aided by the State, which was the central feature of the Elementary Education Act, 1870. The abolition of fees in French elementary schools by Jules Ferry in 1881 was taken as a precedent (though not the only precedent) for the Elementary Education Act, 1891, which virtually introduced free education into England.

3. The administrative influences of French education have not been less important than the political. Among the chief of them may be named the recourse to open competition as a method of filling posts at the disposal of the Government; the idea of higher elementary schools; and the inclination to remove religious instruction from the curriculum of state-aided schools and to substitute for it some form of moral instruction upon a philosophical basis.

**FRIARS.** — See DOMINICANS; FRANCISCANS; MONASTIC EDUCATION.

**FRICK, OTTO** (1832-1891). — A German schoolman; born in Schmitzdorf, near Magdeburg. He received his early education from his father, a Lutheran pastor. At the age of thirteen he entered the Joachimsthal Gymnasium in Berlin, where he came under the influence of Wiese (*q.v.*). In 1851 he became a student in the University of Berlin, but in the following year he went to Halle, where he spent three years in the study of philology and history, devoting some attention also to philosophy and theology. From 1855 to 1857 he was in Constantinople as the tutor of the sons of the Prussian ambassador. After serving for seven years as a teacher in various Prussian gymnasia, he was promoted to a principalship at the early age of thirty-two years, and in 1880 received the appointment as Director of the *Franckesche Stiftungen* in Halle. He renewed the *Seminarium Præceptorum*, which had been founded by Francke, but had ceased to exist since about 1795. This institution became a model for the training courses for teachers of the classical schools that were established in connection with a number of gymnasia in Prussia and other German states. In 1884 he founded the pedagogical magazine, *Lehrproben und Lehrgänge*, in which questions of methodology were treated and model lessons for the higher schools were published. His methods were based on Herbart's pedagogy and tested by his own classroom experience. He insisted on the necessity of a pedagogical preparation for the teachers of the higher schools, and the fact that this necessity is at present generally recognized in Germany is, to a large extent, due to the efforts of Frick.

**FRIENDS, EDUCATIONAL INFLUENCE OF SOCIETY OF.** — **England.** — The influence of the Society of Friends on elementary education in England has been so profound that it is important to consider it in some detail. George Fox (July, 1624—Jan. 13, 1691), the founder of the Society of Friends, was the son of Christopher Fox, a weaver ("righteous Christer"), and was born at Drayton-in-the-Clay, in Leicestershire. He had little education, according to Dr. Hodgkin, "both the spelling and writing of his letters being those of an illiterate person." Before he was twenty, he received a religious "call," and wandered through the country in a species of mystic agony. He began preaching in 1647 at Dukinfield in Cheshire and at Manchester, and in 1648 he first tells us of "a Meeting of Friends" at Little Eaton, near Derby. The influence of Baptist ideas was clearly noticeable. Fox soon had thousands of adherents, whom he calmed and organized. The term "Quaker" at once arose in consequence of a retort made to Fox by one of a bench of magistrates before whom he was summoned. In answer to Fox's exhortation to "tremble at the word of the Lord" the magistrate replied "Quaker." The name occurs in the House of Commons Journals for 1654. At this date Fox was already being helped by Mrs. Margaret Fell of Swarthmoor Hall, whom he subsequently married. Sixty preachers submitted their reports to her in 1654. In the period when all Dissenters were subject to persecution, from 1662 onwards, under the Acts of Uniformity of 1662 and the "Five Mile" act of 1665, the Friends not only kept their meeting houses open, but deliberately opened schools in the teeth of the law. Thus when at Reading in 1664 and at Bristol in 1682 nearly all the adult members were thrown into jail, the meetings were practically kept by the children. In 1667 George Fox advocated the foundation of schools for boys and girls, and by 1671 there were at work more than fifteen Quaker schools. In 1689 there occurs in "The Quakers Remonstrance" (*Harleian Miscellany*, Vol. VII, p. 612) the following significant paragraph:—

"II. That our youth be not suffered to travel abroad, but between twelve and sixteen, and that under the conduct of approved Protestants; for this present way of education is chiefly in pleasure and looseness, which makes way for atheism or popery, no religion or false religion."

The idea of foreign missions was gradually developed, and in 1737 the teaching of foreign languages was commended by the Friends to facilitate the spread of Christian truth. "In 1696 John Bellers' large and interesting plan for industrial education was broached, and in the following year Friends were officially encouraged to provide free education 'for a competent number of the children of poor Friends,' and to arrange for the training of

teachers." In 1702 a school for poor boys was founded at Clerkenwell by the London and Middlesex Quarterly Meeting. It was removed to Islington in 1788, to Croydon in 1825, and to Saffron Walden, where it now is, in 1879. It has changed its character, and is to-day a school for middle-class children of both sexes of the Society of Friends. It is endowed, and admits paying scholars who are not children of Friends. The Friends kept their educational work alive in remarkable fashion during the eighteenth century. In 1798 their deep educational influence suddenly became a national fact, for in that year Joseph Lancaster (1778–1838), already a member of the Society of Friends, set up his famous school in the Borough Road. In the same year an adult school (*q.v.*) was opened at Nottingham, which passed into the care of a Friend, Samuel Fox, and still exists. This was probably the small beginning of the great Quaker adult school movement. Quaker help made Lancaster's work possible on a large scale. Two Friends, William Allen and Joseph Foster, joined the Committee in 1808. In fact, "the movement owed its inception and most of its early support to members of the Society of Friends . . . there was something akin to the very genius of the Society in his whole enterprise. It was at once liberal and religious, practical and philanthropic. It chimed in with their message, and harmonized with their practice." Many are the great Quaker names that lent their support to the movement. In Ireland Lancaster received Quaker support. The Friends had been at work there before Lancaster's time, and had, in 1786, founded a School Society in Dublin, whose schools seemed to have welcomed children of all denominations. Another Friend was one of the great pioneers of modern elementary education in England, W. E. Forster (*q.v.*), who introduced the Education Act of 1870, and whose relatives had done so much for the Lancastrian movement. It may therefore be claimed that a powerful Quaker influence lies behind the great English educational movements of the nineteenth century; and from the point of view of the history of education, it is necessary to remember that this influence is closely related to the revival of elementary education (largely due to the efforts of Dissenters) in the last quarter of the seventeenth century; a revival that the Quakers carried right through the dark days of the eighteenth century. One eighteenth-century school has already been mentioned. To this must be added the Ackworth School, near Pontefract, in Yorkshire, founded by the London Yearly Meeting in 1779 for the children of Friends "not in affluent circumstances." It is a flourishing school to-day, teaching many boys and girls. But the Friends attached themselves to all educational movements. In 1793 were founded the Sunday and day schools at Rossendale in

Lancashire. In 1800 there existed a Friends' school at Lothersdale near Skipton "for the preservation of the youth of both sexes, and for their instruction in useful learning," and at the same date there was another at Nottingham. At Bristol a Sunday school for boys was founded in 1810, and another for girls in 1811. The Friends' Sunday schools were in reality missionary schools for the poor. "At the end of 1910 there were in connection with the Friends First Day Schools Association 248 schools with 2891 teachers and 25,038 scholars, very few of whom were the children of Friends. Not included in these figures are classes for children of Members and Attenders." These classes are usually held before or during a portion of the time of the morning meeting for worship, and distinctly denominational teaching is given. Some reference has been made above to the Adult School at Nottingham of 1798. This seems to have been the precursor of the adult schools started by the Society at Birmingham in 1845, in which reading and writing were the chief inducements offered. "At the end of 1910 there were in connection with the National Council of Adult School Union, 1200 schools for men with a membership of about 69,089, and 683 for women with a membership of about 39,000." It is finally necessary to refer to the Friends Foreign Mission Association, which controls thirty-five schools with 7042 pupils in Syria, India, and the Far East. The educational activities at the present hour of the Society of Friends in England (a small body comprising more than 19,000 persons in full membership) are remarkable indeed, and the historical significance of their work is of the very highest importance. To-day they support secondary and higher educational schools in the following places (the date of the foundation is in parentheses): Saffron Walden (1702); Aekworth (1779); Sidecot, Somerset (1808); Wigton, Cumberland (1815); Bootham School, York. (1823); Mount School, York (1831); Rawdon, near Leeds (1832); Penketh, near Warrington (1834); Great Ayton, Yorks. (1841); Sibford, near Banbury (1842); Dalton University Hall, Manchester (1876); Leighton Park, Reading (1890); the Woodbroke Settlement for religious and social study (1903); Kingsmead (Training School for Foreign Missions), Birmingham (1906); and the Birmingham Training Institute for Sunday School Workers (1907). The Flounders Trust for training teachers (1848), Gibson's bequest for educational purposes, teachers' scholarships for women, the association for promoting the training of women teachers (1870), and the Guild of Teachers (1896) are additional educational agencies.

J. E. G. de M.

**In America.** — When the Friends invaded the American colonies, they brought with them a belief in a thorough, careful, elementary education for all their children, and the mastery, even by the wealthy, of some trade. But as they

made no distinction between clergy and laymen, the incentive which led to the foundation of Harvard, Yale, and Princeton in colonial times did not exist. The divine call was so emphasized that intellectual preparation for the ministry assumed a position of inferior importance. Some of the more narrow even pressed the advantages of ignorance, as making the minister more responsive to heavenly influences. While this attitude was not general, the absence of institutions of higher learning tended to raise a few generations, of most exemplary lives, it is true, and devoted to moral reforms, but with the conceptions of life usually attending a mediocre education. The loss of high intellectual training they felt less keenly, as they adapted themselves to its omission; and it was not till 1856 that the first Quaker college was established. In the meantime the primary and secondary education of Friends and others surrounding them was amply provided for, and in this field rests their claims to general influence and leadership. The colonial schools were day schools, and hence were patronized only by the boys and girls of the locality. They were usually in close proximity to the meeting houses, and attendance at "mid-week meeting" was compulsory on all, Friends and others. These meetings were very simple, but often impressive occasions, and at the least, a valuable discipline in self-control. Wherever a community of Friends existed, whether in city or country, the schoolhouse was an immediate necessity; and as in those days but few other schools existed, it often constituted the educational opportunity of the neighborhood.

The most noted of these colonial schools was the Friends' Public School of Philadelphia. Founded in 1689, with George Keith as headmaster, chartered by William Penn in 1701, 1708, and 1711, each time with a more liberal charter, it was, till the public school system of Pennsylvania was established, the center of the best educational impulses of the city. The central school was a classical school for boys. There were branches in various sections. Some were confined to Friends. Some were for boys and some for girls. Some were free, and others demanded varying payments to accommodate parental resources. Upon the establishment of the state public schools, and the withdrawal of Friends' children to "Select," that is, strictly denominational schools, the patronage was much reduced; and in 1875 the various resources at the disposal of the trustees were combined in one college preparatory school of high grade, of which up to the date of writing (1911) Richard M. Jones has been the only headmaster. This school, now called the William Penn Charter School, is the largest of its class in Philadelphia, and its old boys hold many positions of honor and usefulness in the city and in various colleges and universities.

The Yearly Meetings, which constitute the

largest grouping in the ecclesiastical system of Friends, which were the ultimate authorities and covered the territory from Rhode Island to North Carolina, again and again recommended the establishment of schools. In obedience to such behests, the local meetings would sometimes use the meeting house, or more often would build a separate schoolhouse, and the school would begin in a small way. Such schools were taught by Friends, and patronized by Friends and others. A committee of the meeting would visit them periodically, and closely supervise their operations. They created a desire for education, and practically destroyed all absolute illiteracy. By this general education they prepared the way in many places for the more complete state system which followed.

There were many, probably an unusual number, of self-educated Friends in the eighteenth century. This education was often in special subjects. Botany and the natural sciences had learned devotees, and we read of farmers and tradesmen not a few, who enjoyed classical reading or the solving of mathematical problems. In colonial Philadelphia, as we infer from the *Journal of John Smith* and other sources, there was a group which enjoyed rather wide reading and a scholarly aspect toward life's problems, as well as an earnest and practical appreciation of the responsibility of citizens.

After the Revolution the age of boarding schools opened. They were intended to gather in the better boys and girls from the scattered districts, where good day schools higher than elementary could not be maintained. In 1784, largely through the influence of Moses Brown, a small school was opened in Portsmouth, R.I., which had a struggling existence of four years. Its property was husbanded, and in 1814 the school was reopened in Providence, where it has been in successful existence since, now having the name of its founder. It has always been managed by a committee of New England Yearly Meeting, and has embraced both boys and girls of the college preparatory stage of advancement. Another boarding school was opened at Vassalboro, Me., in 1850. The New York Friends in 1796 founded a school at Nine Partners, N.Y. This was afterwards moved to the shores of Cayuga Lake at Union Springs, and is now the Oakwood Seminary.

In Philadelphia Yearly Meeting there was the strongest educational system. Several day schools of good grade were founded early in the nineteenth century, but the great effort centered in Westtown Boarding School in the country some twenty miles west of Philadelphia. It was a combined effort, though John Dickinson, the "penman of the Revolution," and Owen Biddle, also a Revolutionary official, had as much influence as any in its origin. It was opened in 1799, and, alone among the secondary Friends' Schools of the colonial states,

it has retained its exclusive character, none but Friends being admitted. There is also a system of small primary schools scattered through the country, and a number of excellent secondary day schools in Philadelphia and suburban towns. In addition to the schools managed by committees of the Meetings, there were prior to the establishment of state schools a large number of private academies, schools where much individual work was done, unfettered by the grade system. As many of these were owned by Friends, almost the whole question of primary and secondary education of southeastern Pennsylvania and West Jersey up to 1840 was under Quaker influence.

Baltimore Yearly Meeting started a boarding school at Sandy Springs, Md., which opened in 1817. After a struggling existence of about nine years, it was sold, and the proceeds used directly for the education of Friends' children in other schools. In North Carolina the Yearly Meeting established New Garden Boarding School, now Guilford College, in 1836.

The education in these boarding schools was of a simple, thorough sort. The curriculum in early days was greatly limited, there being but little classics or modern languages. The great staples were mathematics, observational science, and English grammar. The rules were rigid, made by supposedly wise men according to their ideas of right and propriety. The children submitted when they had to, but discipline was largely a game, played on the masters' side with great skill by some, with mortifying failure by others. The dress, language, and habits of Friends were demanded of all, and religious exercises were a necessary and frequent part of the weekly program. This preserved the type in some cases, and produced rebellion and reaction in others. The best were thoroughly trained in fundamentals, and were taught habits of hard work and accurate attainment. In mathematics especially there was unusual proficiency.

Among the men who influenced education in these days were Joseph Lancaster, the eccentric Englishman, who tried to introduce his monitorial system into Philadelphia schools, his apostle John Griscom, of New York, a noted chemist and teacher, Enoch Lewis, John Gummere and Benjamin Hallowell, accomplished mathematicians, and John For-sythe, a Scotch-Irish immigrant. Lindley Murray and Gould Brown, the grammarians, were both Friends.

It was due to the efforts of Friends, and based on their institutions as models, that the public school system was started in several places. In New York City a free school for girls not belonging to any denomination was started in 1802 by Friends. This led to the establishment soon after of other schools for boys and to the society of which De Witt Clinton was president, from which the city

system resulted. A large proportion of his supporters were Friends. The Free School Society was formed in 1805, and in 1825 the name was changed to the Public School Society (*q.v.*). It was devoted to giving non-church children of the poorer classes an elementary education, which included Biblical instruction. In Philadelphia the Adelphi and Aimwell schools, the latter still existing, for boys and girls respectively, were formed about the year 1808, for similar purposes, and some of the public schools were doing the same work. These helped to form public opinion in favor of general education. In 1827 the Pennsylvania Society for the promotion of Public Schools supplied the popular support for the movement, then pending. Roberts Vaux, a Friend, was president and leading man, and Dr. George Smith in the legislature was active in perfecting the system.

While Friends were thus giving an impetus to public instruction, many of their members, when they found that it involved double taxation for them if they maintained their own schools, were at least lukewarm in its support, and the Quaker districts already well supplied with schools were slow to take advantage of state laws.

The "Separation" of 1827, which divided the Society of Friends into two opposing bodies, resulted in a duplication in part of the system. The "Orthodox" Friends retained the majority of the old schools, while the other body established new day schools in New York, Philadelphia, and Baltimore, the George School, a boarding school in Bucks County, Pa., and a number of smaller schools covering the country districts. The migration of Friends to the westward resulted in the establishment of large meetings at first in Ohio and Indiana, then in Iowa, Kansas, Oregon, and California. Great numbers moved from North Carolina to escape slavery and its consequences. With them went at first their little schools, then their boarding schools and academies. Many of these did not prosper, for the public school system in some cases antedated them, in others followed close on their heels. In eastern Indiana, especially, the little Friends' schools connected with every meeting were potent in their influence for good, and educated a great number of men and women who as teachers extended that influence widely.

About 1850 the collegiate era began. Haverford School, near Philadelphia, founded in 1833, became Haverford College (*q.v.*) in 1856, though prior to this date its work was largely of a collegiate grade. Swarthmore College (*q.v.*) in the same neighborhood opened its doors both to boys and girls in 1864, and Bryn Mawr College (*q.v.*), for girls only, in 1885. These three institutions, though not large, are well endowed, well-built colleges of high grade, situated in beautiful parks and maintaining excellent faculties. New Garden School,

North Carolina, became Guilford College in 1889. The boarding school at Richmond, Ind., became Earlham College (*q.v.*) in 1859, and there followed within a few years the establishment of Wilmington College, Ohio, Penn College, Iowa, Friends' University, Kansas, Central College, Nebraska, Pacific College, Oregon, and Whittier College, California. These constitute, with a few academies, the whole of the Quaker school system west of the Alleghanies, the primary and secondary education having been handed over to the public school system. In the East, especially in and around Philadelphia, the whole line of schools still exists in undiminished efficiency. The Western colleges are not heavily endowed. All but Earlham have preparatory departments, which in some cases have larger enrollments than the colleges. In the East the colleges are under the care of self-perpetuating boards of trustees, who are generally Friends; in the West they are organically connected with the Yearly Meetings and managed by their committees. Outside of their own colleges, Friends have had some share in the development of higher education. Moses Brown greatly aided Brown University, though the man for whom it was named, a relative, was not a Quaker. Ezra Cornell and John Hopkins, who founded the universities which bear their names, were Friends.

The education of Friends has always been characterized by thoroughness in the fundamental subjects. They have not yielded to the frequent diversions to new methods and objects which have been a part of our American system. This conservatism has been in some respects a disadvantage, but it has had the effect to produce honest, effective scholars so far as they have gone. This discipline has also reacted on character, so that the products of Friends' Schools have but seldom proved tricky or superficial men in business or politics.

Friends have always demanded in their schools what they have meant to be effective religious instruction. Until the last half century this has been confined to memorizing Scripture texts, and required attendance at the simple religious exercises of Friends, largely silent, and always without music or prearranged speaking. On some this discipline has produced great seriousness, on many others it has seemed to be entirely without effect. The moral results have been of a high order. Whether by the strict regulations of the earlier days, or the more liberal coöperation with student activities of recent times, a standard has been maintained which has given them some reputation, both as to the internal conditions and the resulting character.

In recent years there has been a strong drift among Friends toward graduate instruction in the great universities. The effect of this is strongly felt upon the society. The old jealousy of learning has disappeared, and

the schools of all grades are feeling the impulse. With a considerable adherence to conservative methods, and a sentiment for honest statement and simple living, there is also a growing demand for real scholarship in all fields of learning, and its proper liberalizing effect upon thought and character.

I. S.

**FRIENDS' UNIVERSITY, WICHITA, KANS.**—A coeducational institution, opened in 1898 under the auspices of the College Association of Friends, under a state charter received in 1891. Preparatory, collegiate, normal, commercial, musical and biblical departments are maintained. Students are admitted on a high school certificate or by an examination, the requirements for which are equivalent approximately to fifteen units. There is a faculty of twenty-one members.

**FRIEZE, HENRY SIMMONS (1817-1889).**—College professor and educational writer; was graduated from Brown University in 1841. He was tutor at Brown from 1841 to 1845, and principal of the preparatory school connected with the university from 1845 to 1854. During the next thirty-five years he was professor in the University of Michigan, and during three periods (1869-1871, 1880-1882, and 1887-1888) acting president of the university. Author of *Ancient and Modern Education*, *Life of President Henry P. Tappan*, a series of Latin texts, and numerous articles on education. W. S. M.

**FRISIUS.**—See GEMMA FRISIUS.

**FRÖEBEL, FRIEDRICH (1782-1852).**—The founder of the kindergarten, and exponent of a philosophy of education which has exerted an ever-widening influence upon other educational institutions; was born at Oberweissbach, a village of Thuringia, in 1782.

*Biography.*—The early childhood of Froebel was somewhat unhappy. His mother died during his first year, and the austerity of his father, who was minister of the parish, led to an estrangement that was very keenly felt by the younger Froebel. He was rescued from the neglect and harshness of a stepmother by his uncle, another clergyman, but of a more genial type than the elder Froebel. With this uncle at Stadt-Ihm Friedrich remained for five years, reasonably happy in his lessons, more than happy in his observation of animals and plants and in the society of his schoolfellows. In 1797 he was apprenticed to a forester at Neuhaus, where he studied geometry, botany, and mathematics, and even found occasion to attend and enjoy a performance of Iffland's *Huntsmen*. The forester, indeed, taught him nothing, but to disguise his neglect made an ill report of the youth to his father. By a fortunate chance the young Froebel was enabled to visit one of his brothers during the year 1799 at Jena. There for a time he attended lectures; but having fallen into debt, returned home and comforted his father in his last days. Froebel then became an actuary at Bamberg, and subsequently an accountant in Baireuth and later in Mecklenburg. At Bamberg he became interested in the philosophy of Schelling, which directly and indirectly was to exercise a great influence over his own world view. In 1805 Froebel went to Frankfurt to pursue the study of architecture, but allowed himself to be deflected from his purpose by Grüner, the director of the normal school, who persuaded him to become a teacher. He now felt as a bird in the air, a fish in the water, and on his first holiday took occasion to visit Pestalozzi in Switzerland. After two years under Grüner, he decided to resign in order to prosecute his own studies; but was persuaded to accept the tutorship of three boys, with whom he seems to have laid the foundation of certain of the kindergarten occupations. In 1808 he journeyed with his pupils to Yverdon, and there lived in close association with the Pestalozzian institution, which fortunately served to stimulate his enthusiasm for education, without engendering in any way the conviction that its problems had been solved. Froebel returned to Frankfurt in 1810, and in July, 1811, he proceeded to the University of Göttingen. By this time his definite aim was to find how to educate a human being scientifically; and it is significant in his educational philosophy that his researches for this purpose were primarily made, not among children, but in the fields of chemistry, physics, mineralogy, and natural philosophy. Natural

objects were to Froebel the keystone to the life of men. In October, 1812, Froebel was attracted by the lectures of Weiss and Savigny to the University of Berlin, where he became in the meantime a teacher in the school of the Pestalozzian Plamann (*q.v.*). In 1813, however, he joined in the war of liberation, although, as he remarked, "no Prussian," and ill-fitted by constitution for the rigors of the war. "It was hardly possible for me to conceive how any young man capable of bearing arms could think of becoming an educator of children whose country he would not defend with his blood or his life." As a soldier Froebel won the friendship of Langenthal and Middendorf, afterwards faithful associates in his life work, through whom his philosophical interest in Fichte (*q.v.*), Schleiermacher, and Neander (*q.v.*) was aroused and thoroughly established.

Having seen nothing of the field of battle, Froebel was back in Berlin University in 1814 as assistant to Professor Weiss in the mineralogical museum. At this time he declares that he studied profoundly the works of Rousseau, Pestalozzi, Basedow, and Fichte on education; and when the death of his brother Christoph in 1816 left him the guardian of Christoph's children, it naturally occurred to him that here was the nucleus of a school to be conducted upon a psychological and scientific basis. The outcome of his new determination was the foundation of the Universal German Educational Institute at Griesheim, transferred in 1817 to Keilhau. Thither came Langenthal and Middendorf. In 1808 Froebel had taken to himself a worthy wife in Mlle. Henriette Wilhelmine Hoffmeister, herself a student of Fichte and Schleiermacher, a woman to whom Froebel owed more in his subsequent institutional work than has yet been generally recognized. From this time Froebel began to be a prolific writer. The *Education of Man* appeared in 1826; and the admirable autobiographical letter to the Duke of Meiningen was written in the following year. In 1828 Froebel drew up a plan for a national educational institute at Illeba, for which he vainly expected the support of the Duke of Meiningen; the plan, however, is still the basis of many of the kindergarten occupations. In 1831 Froebel was again in Frankfurt, whence he accepted the call to open a school at Wartensee, which was soon afterwards transferred to Willisau. In 1833 he had got as far as offering a training course for teachers at Burgdorf, where in 1834 he founded an orphanage. From 1836 his peculiar attraction to young children became more manifest than had hitherto been the case; and the institutions founded in 1837 at Blankenburg, the first kindergarten, although the name was not adopted till 1840, and in 1839 in Berlin, were for little children only. But in 1839 the death of his wife came as a severe trial to the enthusiastic teacher.

The era of kindergartens was, however, now at hand. It dates from the opening of a school for little children at Blankenburg on June 28, 1840. Kindergartens were subsequently opened in Rudolstadt, 1840, Gera, 1841, and Darmstadt, 1844. The gates of the future seemed wide open, and by the year 1847 there were ten additional kindergartens. In 1848 Froebel was occupied with a congress of teachers at Rudolstadt and a training course which he conducted at Dresden; and in 1849 he opened a kindergarten training school at Liebenstein. During this period of his life Froebel suffered bitterly from the attacks of calumny, but his friends stood faithfully by him; and in 1851 he found consolation in a second marriage, with Mlle. Luise Levin. There was need of every reinforcement, for the severest blow of all, the prohibition of kindergartens in Prussia by order of Von Raumer (*q.v.*), fell with all but crushing force upon the little band of enthusiasts on Aug. 7, 1851. Froebel rallied to attend the educational congress held at Gotha in April, 1852, at which he was welcomed with great honor; but his strength was exhausted, and on June 21, 1852, he died.

*Froebel as a Student.*—The originality of the philosophy of Froebel has been frequently overrated, for his opinions were derived, directly or indirectly, in the main from Fichte, Schelling, and Krause; but it is apt to be forgotten, on the other hand, that he was a man of wide and deep reading. He studied, for instance, Winckelmann's *Letters on Art*, the *Zendavesta*, Schelling's *Bruno*, and *On the World-Soul*, Pröschke's *Fragments of Anthropology*, Novalis's works, Arndt's *Germany*, and *Europe*, Pestalozzi's works, Arndt's *Fragments of Human Culture*, Seiler's educational works, Richter's *Levana*, Krause's works, Nägeli and Pfeifer's *Treatise on the Construction of a Musical Course according to the Principles of Pestalozzi* (which influenced the prominence afterwards given by Froebel to music in the kindergarten), Förster's *Travels in Rhineland*, Fichte's *National Education*, and doubtless many other works, from a number of which quotations are to be found prefixed to his articles in the *Sonntags-Blatt* and other journals.

*Froebel's Relation to Pestalozzi.*—Froebel's attitude as a pupil of Pestalozzi was not merely receptive and appreciative, but also highly critical. Pestalozzi emphasized handicraft for its value in physical training and technical preparation for vocation; Froebel for its inward correlative experience, which might be expected to contribute to the completeness of a human being. Froebel cared nothing for the merely mechanical in education. Again, Pestalozzi was more satisfied with the principle of observation *per se* than was Froebel, who insisted upon combining observation with activity. Pestalozzi, moreover, made home education central; Froebel

aimed at the adaptation of the life of the child to all his institutional relationships, especially, for example, to his duties as a citizen. Froebel wrote of the Pestalozzian education: "The power and many sidedness of the educational effort made up for deficiency in unity and comprehensiveness; the love, the warmth, the stir of the whole, the human kindness and benevolence of right, replaced the want of clearness, depth, thoroughness, extent, perseverance and steadiness." Froebel aimed at a greater unity of effort in the direction of means and ends. Pestalozzi's work in arithmetic, drawing, and language on the formal side, his *Mother's Book* on the social side, and the nobility of his educational intuition on the personal side, were of profound influence upon the development of Froebel's theories of education and his life.

*Froebel's Philosophical Relations.* — Froebel's was not a superficial educational theory, but rather a philosophy of life applied to education. Profoundly influenced by the idealist and romanticist thought of his day and nation, he appears to draw his inspiration now from Schelling, now again from Fichte. In general, he follows Schelling when his discourse is of nature, or of symbolism, or when he takes an æsthetic view of things; but Fichte whenever he thinks in terms of morality, ends, personality, will, duty, or citizenship. He had been introduced early in life to the works of Schelling, while his most intimate friends and his first wife were disciples of Fichte. To Fichte and Schelling, therefore, one must turn to appreciate the full implications of his philosophy of life and education. Among the philosophers contemporary with Froebel, Krause, who became his friend and adviser, had already effected a similar synthesis; and Krause's *Ideal of Humanity* is the prototype in some respects of Froebel's *Education of Man*. Among the fruits of the friendship of Froebel and Krause should be enumerated the long biographical letter of the former to his philosophical friend, and the gift to Froebel of Krause's books. Krause was responsible for the introduction of Froebel to the invaluable works of Comenius.

*Froebel's Educational Philosophy.* — The most systematic treatise on education by Froebel is the *Education of Man (Menschen-Erziehung)*, which first appeared in 1826 in connection with the work of the Institute at Keilhau. Here Froebel discusses man as a child of nature, of humanity, and of God. All things, he claims, are pervaded by a universal law, and by an underlying unity, which is God. The destiny of all things is to reveal this underlying unity; and man has not only to reveal this unity, but to consciously realize it as the divine essence of his nature. "Education consists in leading man, as a thinking, intelligent being, growing into self-consciousness, to a pure and unsullied, conscious and free

representation of the inner law of Divine Unity, and in teaching him ways and means thereto." The original nature of education is to be passive, a removal of hindrances to the development of life from within. Why does man, alone of all things, close his mind to the silent teachings of nature? The teacher ought to assume the existence of an unmarred original state in every human being, until the opposite fact is clearly demonstrated. If children's natures are unmarred, the eternal principle lives in them, and an interfering and mandatory education can do nothing but mischief. The imperative mood in moral instruction is only to be employed by the teacher, when between himself and the pupil there exists the invisible rule of a third something, the *right*, the *best*, which both pupil and teacher recognize to be sovereign. Man should be viewed and treated as having in himself unity, diversity, and individuality, corresponding to the threefold aspect of his nature as divine, natural, and human *per se*. Each human being should spontaneously represent these three phases in action. This is the doctrine of *self-activity*. The primary function of education is to permit self-activity to be manifested, but secondary functions are to correct aberrations and provide such means as experience has proved to be suitable. The external act is to be simply the manifestation of the spiritual nature that is the essence underlying every individual life. This, according to Froebel, is the great message also of Christianity. The teacher is to nurse the divine nature of the child; this is the method of all education.

*Froebel's Teaching concerning Infancy.* — In his account of infancy Froebel wavers between empirical child study and general philosophy. The child's first self-expression is to put forth force, whence comes the experience of resistance, which he greatly enjoys. Soon appears sympathy, manifested in his smile, which also reveals the beginning of self-consciousness. His unrest, tears, and little sorrows are to be investigated, and their cause removed. The most fatal development, which should be in every way guarded against, is apt to be willfulness. The early life of the child must be surrounded with cleanliness, purity, and truth. Above all, the feeling of community with others, resting as it does on an ultimate spiritual identity in human nature and even in things regarded as inanimate, ought to be cherished and brought into consciousness, when the opportunity arrives. A religious spirit brought into the nursery is the most supreme and permanent benefit that can be conferred on the future life of the child. "Let no one say the children will not understand it, for thereby he deprives them of their greatest good. If only they are not already degenerate, if only they are not already too much estranged from themselves and their parents, they understand it, and will understand it."

they understand it not through and in the thought, but through and in the heart." The life of man is a continuous development from infancy, and because this is so, the stage of infancy is more vitally important to education than is generally realized or confessed. From his very infancy, a man should be exercised in creativeness and productive work, with singleness of purpose and in obedience to the inner law of human nature.

*Froebel's Teaching concerning Early Childhood.* — Objects come to the child out of an unknown void, at first as separate and isolated things, but afterwards in their relations and individualities. In this process the child gradually distinguishes himself from external things, and at last comes to the period of the dawn of reason, just as in the development of the race before him. Thus the life both of the individual and of the race is a continuous whole, which develops according to a divine design. It was Froebel's conviction that this development always involves a contrast between *opposites*. He held that, just as in our thinking we are accustomed to analyze and put together again, so we find that objects in their actual occurrence are found to exist and develop in the form of opposites and reconciliations. (This view was apparently a confusion of a method of thought with a law of life.) Froebel described the development of the senses in accordance with this law rather than by observation, and wrongfully put sight after hearing as an opposite stimulated by it. Early movements should be watched with a view to prevent the occurrence of such as have no inner meaning. The child's first language, plays, and views of external things are worthy of careful attention and rectification. "The *plays* of childhood are the germinal leaves of all later life." "Play is the self-active representation of the inner from inner necessity and impulse." Food and clothing are to satisfy the simple needs of nature. The mother will educate the child's sensations and early associations of ideas conscientiously, yet carefully. Drawing, in which at first the child may discover for himself a crude pleasure in the mere change of surfaces, will soon open a new world to him. Drawing, in its turn, will naturally lead to number. Indeed, the child's life is full of its own interests; we should use this richness, and not disregard or stifle it. It is the adults that are dull; let them live for and with their children. This is, indeed, the great message of Froebel to humanity. "Let us learn from our children, let us give heed to the gentle admonitions of their life, to the silent demands of their minds. Let us live with our children; then will the life of our children bring us peace and joy, then shall we begin to grow wise, to be wise."

*Froebel's Teaching concerning Boyhood.* — There comes a time when the child passes into boyhood, the test being not one of age, but of analytical power manifested in the distinction

of things from names and self from objects. Hitherto the watchword has been training, guidance; now it becomes instruction. The basis of instruction lies not wholly in the nature of the human being, but in the natural laws that govern both human beings and external things. The boy goes to school; and the true meaning of a school is "the conscious communication of knowledge, for a definite purpose and in definite inner connection." The primary aim of the school is to secure firmness of will for the boy; and to this end all his activities should proceed from and refer to the development of the internal. The necessary conditions are precept, example, and a good heart that is the outcome of proper influences upon early childhood. Of these influences, the chief are the life of play and of family relations. The boy, as well as the child, stands in need of these reinforcements; but his care is less for the activity as such, and more for its results. He loves to overcome obstacles. "To climb a new tree means to the boy the discovery of a new world." He collects, he models, he cultivates, he builds. By his experience of the present he becomes aware of the existence of the past; and this opens the door of story-telling and history. He rejoices in song. He seeks to understand himself and nature. His manifold self-expressions are symbols of an inner, spiritual life; and for parents and teachers the only clues to its nature. This is indeed a description of ideal boyhood. There may be shortcomings or perversions due to two causes: "in the first place, the complete neglect of the development of certain sides of full human life; secondly, the early faulty tendency — the early faulty and unnatural steps of development and distortion of the originally good human powers and agencies by arbitrary and willful interference with the original orderly and logical course of human development." But man is originally good; created with and for truth. His so-called original depravity is merely bad habit. "The boy is only satisfied when he has found Him to Whom he has been drawn by indefinable yearning, because only then will he have found himself."

*Froebel's View of the School.* — "The school endeavors to render the scholar fully conscious of the nature and inner life of things and of himself, to teach him to know the inner relations of things to one another, to the human being, to the scholar, and to the living source and conscious unity of all things — to God." In the school, therefore, the boy receives an insight which is of a different order from his previous superficial view of things. An intelligent consciousness, that of the master, mediates between the outer world and the scholar, and gives them mutual understanding. However powerless the village schoolmaster may feel to fulfill the requirements of this definition, the child has faith in him, and this makes all things possible, accomplishes all things. The

vivacity and intensity of schoolboys ought to be regarded as a spiritually quickening power. "It is the spirit alone that makes the school and the schoolroom. . . . Never forget that the essential business of the school is not so much to teach and to communicate a variety and multiplicity of things as it is to give prominence to the ever-living unity that is in all things." Instruction and the school are to lead man to a life in full harmony with the knowledge of man, nature, and God. The poles of boy-life are the mind and the outer world, and language, which unites the two.

*Froebel's Theory of the Organization of Studies.*—The right grouping of studies in accordance with the inner nature of man appeared to Froebel to involve in the curriculum: (1) Instruction in religion, which assumes some degree of the religious spirit; it quickens the soul, and gives some insight into the nature of the divine. The human spirit is related to God as the thought to the thinker, the son to the father, related not in a material, but a spiritual union. To realize this relation is to be a Christian; in this sense, therefore, the school should first of all teach religion. (2) Natural science and mathematics. Nature represents what religion reveals, fulfills what religion demands. There can be no true contemplation of nature without the recognition of its relative unity, divine origin, and progressive development. God is the great artist; man and nature his cherished works of art—not mere art masks, but the revelation of the most inner divine personality. In nature man sees his aspiration, his destiny, his mission; and nowhere more clearly than in plants, especially trees. The life of trees is a revelation of human life, not alone in the individual, but also in the race, for the development of the human race is parallel to that of the individual man. The reason that a study of nature is so suggestive for the life of man is the common origin and subsistence of nature and man in God. In nature the ultimate cause of all things is force. Force naturally tends to exert itself in all directions equally, as it were, in a spherical way. The sphere is therefore the fundamental natural form, the form of the largest and smallest objects in nature, planets and particles. By variations in the planes and directions of tension, other forms than the spherical are derived. The first phase in material formation is represented by crystals. The form of the crystal represents the relative intensity in the different directions of the inner force. (Froebel believed that the analogy which he thought he had discovered between crystalline and human education throws important light on the development of man.) The action of inner forces from the center of a crystal will produce first a cube, second an octohedron, and third a tetrahedron. Other forms are derivative from these. All natural objects resemble crystals in proceeding

from a heart point in their development; in fact, all may be grouped as crystalline, vegetable, and animal. Plants advance upon crystals, in exhibiting the inner force, "not only in multiplied diversity, but also in a state of progressive changes." For purposes of his theories, Froebel seized upon the fundamental concept of organism as described by Kant and the idealistic philosophers of the day. "The essential nature of the whole plant lies in some peculiar manner in each individual part of the plant." "Thus, inasmuch as the law of the individual part is repeated in the whole, the totality of all mundane forms, although but a small part of the great universe, is nevertheless, relatively, a great, individual, organized, and organic whole." Animals, again, constitute an organic whole. In animals and in nature generally the law is that the external becomes internal. With such a symbolic view of nature, Froebel desired above all things that the boy should be taught at an early period "to see nature in all her diversity as a unit, as a great living whole, as one thought of God." Fragmentary study of nature deprives it of life and impairs the vigor of the mind. Technical terms may wait; the things of nature themselves are a ladder between heaven and earth; number is a reliable guide in their diversity. Mathematics mediates between man and nature, between the laws of thought and the diversity of natural forms. Mathematics is the expression of life as such; and education without it is "a weak, imperfect patchwork." (3) Language. As religion manifests being, a unity, as nature manifests energy, diversity, so language strives to manifest life,—the connection of being and energy, of unity and diversity. All three seek to make the internal external; that is, all are modes of self-expression. Language represents, on the one hand, natural energy lifted into life, on the other, the human mind lifted into self-consciousness. Its ultimate roots express natural as well as spiritual operations. Language is therefore not purely conventional, or at least not arbitrary, but conforms to law, and should be taught according to its law. Accordingly, the language teaching of Froebel, like his science and natural philosophy, was symbolical; for example, he taught that in general, consonants indicate what is external, or force; vowels what is internal, or spirit. Language arises from an inner want of communication among men; and from a similar felt want its teaching should as far as possible proceed. "Writing is the first chief act of free and self-active consciousness." (4) Art and education in art. Art, in the process of education, must be regarded as the pure representation of the inner. It may be said to take the form of music, drawing, painting, or modeling, according as its material consists of tones, lines, surfaces, or solids. The schoolboy is not to be educated as an artist, but rather to appreciate

art, and understand it. In art, as in everything, the clear representation of man as a divine, human, and natural being is the supreme aim of education. P. R. C.

**FROST, JOHN** (1800-1859). — Textbook author; graduated at Harvard College in the class of 1822; and for many years engaged in educational work in Philadelphia and Boston. He was the author of twenty-nine school books, including readers, speakers, grammars, and histories. W. S. M.

**FULDA, MONASTERY OF.** — One of the most famous centers of learning in the early Middle Ages. It was founded in 744 by St. Boniface (*q.v.*), assisted by Sturmian, a Bavarian noble who was sent to study the Benedictine Monastery at Monte Cassino, under the Benedictine rule. In a very few years the monastery rapidly increased in numbers, and gained a great reputation. But it did not attain the height of its fame until the ninth century, when the school was placed under the direction of Rabanus Maurus (*q.v.*), a favorite pupil of Alcuin (*q.v.*), and organized in direct imitation of the school at Tours. Einhard (*q.v.*), Servatus Lupus (*q.v.*), and Walafrid Strabo (*q.v.*) were among the most renowned pupils. Abbots from all parts of Germany, as well as nobles, sent pupils to be educated here. Twelve copyists were kept constantly at work, and under Rabanus' influence a library was

instituted, which lasted to the seventeenth century. In the school there were twelve teachers, under the direction of a principal, who assigned the courses of lectures to be given. In keeping alive a study of the classics, Fulda may be numbered among the leading seats of learning in the medieval period.

**FULLER, SARAH MARGARET** (1810-1850). — The Marchioness of Ossoli; educated in the public and private schools of Massachusetts. She conducted a school in Rhode Island for some time, but was best known in education by her association with A. Bronson Alcott (*q.v.*) in the Temple School at Boston. She contributed several papers on education to the journals of the time. W. S. M.

- HIGGINSON, T. W. *Sarah Margaret Fuller*. (Boston, 1884.)

**FULLER, THOMAS** (1608-1661). — Biographer, historian and divine, born at Aldwinchle in Northamptonshire. In the history of education, Fuller is important for the biographies of learned men to be found in the *Abel Redivivus*, 1651; and in the *Worthies of England* (1662); and for his *History of Cambridge University* (1655). His more general historical works, *History of the Holy War* (Crusades), 1639, and a *Pisgah-sight of Palestine* (1650), Bible history and geography of Palestine, attempt graphic descriptions likely to make history popular both by the subjects chosen and the method of treatment. Fuller's views on the good school-master, on "the general artist" (*i.e.* the student in academic arts subjects in the university), on the good master of a college, are to be found in the *Holy State and the Profane State* (1642). He was a man of wide scholarship and vast memory. He is distinguished by his decisiveness of view in political and religious affairs, and yet a certain humanism that led him to escape the intolerance of the times. F. W.

**FUNCTION.** — Any process, sufficiently complex to involve an arrangement or coördination of minor processes, which fulfills a specific end in such a way as to conserve itself, is called a function. This may be illustrated by digestion. There are a number of chemico-

physical processes sustained by various structures that cooperate together in such a way as to restore the wasting tissues of the body, the specific end; at the same time the processes react so as to maintain the conditions of their own maintenance. The sum total of functions, in their reciprocal adjustment to one another, constitute life, which, accordingly, is defined in the same way as a function. Life (or functions, activities) includes within itself the distinction of organism and environment (*q.v.*).

The transfer of the conception of functions from biology to philosophy is a mark of a general tendency (1) to substitute a dynamic theory for a static one; (2) to place ends and purposes within the process of life experience instead of outside and beyond; and (3) to emphasize the continuity of process of development through biological, psychological, and social activities. In educational theory the fundamental character of the category of function is exemplified not merely in the increasing use of biological concepts, like adaptation (*q.v.*), but in the attempt to introduce into the school modes of active occupation which involve control of materials and tools in a process of realizing results which are felt to possess immediate or intrinsic value. J. D.

**FUNCTION.**—In Mathematics.—A quantity that depends upon another quantity for its value, varying in general as the other quantity varies, is called a function of that quantity. Thus the area of a square is a function of its side, the area of a rectangle is a function of its base and its altitude, and interest is a function of the principal and the rate and the time. In general, the expression

$$a_0x^n + a_1x^{n-1} + a_2x^{n-2} + \dots + a_{n-1}x + a_n$$

is an integral function of  $x$ , it being understood that  $a_0, a_1, a_2, \dots, a_n$  are given numbers, and that  $n$  is a positive integer. This expression may be written  $f(x)$ ,  $x$  being the variable. If  $a_n$  is not zero, then this expression is said to be a function of  $x$  of the  $n$ th degree. In the theory of equations symmetric functions of the roots play an important part. Symmetric functions of the roots are functions in which all of the roots enter in the same way, so that the expression is unaltered in value when any two of the roots are interchanged. For example, if the roots of a quadratic are  $x_1$  and  $x_2$ , then the following are symmetric functions of the roots:—

$$x_1 + x_2, x_1^2 + x_2^2, x_1^2 + x_1x_2 + x_2^2, \text{ etc.}$$

Given the general equation

$$x^n + a_1x^{n-1} + a_2x^{n-2} + \dots + a_{n-1}x + a_n = 0,$$

the roots being  $x_1, x_2, x_3, \dots, x_n$ , and letting  $\Sigma x^n$  stand for the sum of the  $n$ th powers of the roots (a symmetric function), we have

$$\begin{aligned} \Sigma x &= -a_1, \\ \Sigma x^2 &= a_1^2 - 2a_2, \\ \Sigma x^3 &= -a_1^3 + 3a_1a_2 - 3a_3, \\ \Sigma x^4 &= a_1^4 - 4a_1^2a_2 + 4a_1a_3 + 2a_2^2 - 4a_4. \end{aligned}$$

Similarly other symmetric functions are known and can be expressed. An important branch of mathematics is concerned with the theory of functions of a complex variable. (See COMPLEX NUMBERS.) Such functions deal with complex numbers of the form  $x + yi$  where  $x$  and  $y$  are real numbers and  $i$  stands for  $\sqrt{-1}$ . These complex numbers stand for points in a plane, just as  $x$  and  $y$  stand for points on two arbitrary axes. Such complex numbers may be represented by  $z, z', z'', \dots$ , and it is possible to have  $z'$ , a function of  $z$ , just as it is possible to have  $y$  a function of  $x$ .

Besides these algebraic functions of a real and of a complex variable, we have various other kinds of functions. Of these one of the simplest is the trigonometric function. (See TRIGONOMETRY.) Thus we have  $\sin x, \cos x, \tan x, \cot x, \sec x$ , and  $\csc x$ , making the six trigonometric functions usually studied.

The idea of function is of late entering more prominently into the work of elementary mathematics. Teachers will find that graphic work in algebra is an important aid in making the concept clear to high school pupils. There is no need for emphasizing the idea very much, although it undoubtedly has a place in algebra and geometry. D. E. S.

**FUNCTIONAL PSYCHOLOGY.**—See PSYCHOLOGY, FUNCTIONAL.

**FUNDAMENTAL AND ACCESSORY.**—See MUSCLES, FUNDAMENTAL AND ACCESSORY.

**FUNDAMENTALS.**—A term applied by popular usage to those school subjects which give a command over the written or printed expression of knowledge. It is thus fundamental to know how to read, for all knowledge acquired by any other means than direct personal experience or the speech of others can only be gained through ability to gain the thought from print or script. It is also fundamental to know how to write, spell, and compose sentences in order to communicate one's own thoughts through a written record. Arithmetical calculation is also a fundamental, since it involves the reading, writing, and manipulating of quantitative symbols. Hence the fundamentals of the course of study, as popularly cited, are the formal subjects, that is, reading, writing, spelling, English composition, and arithmetic. Grammar, because it is felt to be intimately related to English composition, is traditionally included. There is a distinct

tendency of late, even among laymen, to include the subjects which provide fundamental facts, as well as those which give mastery over the fundamental forms and symbols of writing and printing. Hence it is not unusual to see geography and history, the older of the content subjects, included. On the same basis the studies of literature and natural science, with a more recent place in the curriculum, tend to be included. Thus the distinction between fundamentals and other school acquisitions inevitably tends to break down, even in popular acceptance. To the thoughtful educator any symbol, skill, or fact requisite to a successful life is a fundamental, and any subject which provides the opportunity to acquire some necessary tool, information, attitude, or discipline is fundamental. Thus in a more accurate and broad sense such subjects as manual training, drawing, music, and physical education may be regarded as fundamentals, and the term then ceases to have significance.

See FORM AND CONTENT.

**FUNDS, APPORTIONMENT OF.** — See APPORTIONMENT OF SCHOOL FUNDS.

**FUNDS, SCHOOL.** — See SCHOOL FUNDS; BUDGET, SCHOOL.

**FURMAN UNIVERSITY, GREENVILLE, S.C.** — The outgrowth of the Furman Academy and Theological Institution, established at Gagefield in 1827, which after a chequered career was moved to its present location with its present title in 1851. The institution is under the control of the Baptist State Convention. A preparatory department is maintained in addition to the college. Admission is by certificate from a high school, or by meeting requirements demanding about eight points of high school work. Courses are offered leading to the degrees of B.A., B.Sc., and M.A. There is a faculty of twelve members.

**FURNITURE, SCHOOL.** — See ARCHITECTURE, SCHOOL; DESKS.

**FURNIVALL, FREDERICK JAMES** (1825–1910). — An English scholar. He was the son of a surgeon at Egham, Surrey, where he was born Feb. 1, 1825. After a boyhood passed in various semi-private schools and a year at University College, London, he became a student of law at Trinity Hall, Cambridge, and was called to the bar in 1849. But he soon deserted the law for literature and education through his devotion to the social and intellectual advancement of the working classes. The least clerically-minded of men, he fell under the influence of a clergyman, also of Trinity Hall, who had deserted law for theology, Frederick Denison Maurice (*q.v.*), and became one of his principal lieutenants at the Working Men's College in Great Ormond St., Lon-

don, which he founded on Oct. 30, 1854. Furnivall remained a constant teacher and friend of the college for the rest of his life, was for a long time captain of its Rifle Volunteer Corps, president of its rowing club, and a leading promoter of its social life. He took up the study of English language and literature, and was for many years Honorary Secretary of the Philological Society, and joint and then sole editor of the *New English Dictionary*. Even after it was removed, in 1885, to Oxford and placed under Dr. Murray's editorship, Dr. Furnivall's time was largely employed in unpaid researches for it. By the *Dictionary* and the numerous societies which he started, and the numerous volumes which he edited for them, Dr. Furnivall did more than any one to promote the study of the English language, literature, and history, and to enforce the entrance of these subjects into the curricula of schools and universities. The Early English Text Society was founded in 1864, the Chaucer Society and the Ballad Society in 1868, the New Shakspeare Society in 1873, the Wyclif Society in 1882, the Shelley Society in 1885, and, sole instance of a poet's works becoming the prey of expositors in his lifetime, the Browning Society in 1881. In his own *Babees Book*, with the alternative title of *Manners and Meals in the Olden Times*, published by the Early English Text Society in 1868, Dr. Furnivall, in the text and still more in the Forewords, laid the foundation of the history of education in England. An eager researcher and worker in these fields to the last, he died at the age of eighty-five on July 2, 1910. A. F. L.

**FÜRSTENSCHULEN.** — Schools established by princes, somewhat in imitation of the Italian court schools. They form one of the earliest types of state schools established from the confiscated property of monasteries and churches in Saxony. They originated in an ordinance issued in 1543 by Duke Maurice of Saxony, to the following effect: "And since it is necessary for Christian doctrine and conduct and for all good ordinances and government that the youth should be brought up to praise God and obey him, and should be instructed and taught the language and arts and above all the Holy Writ, that in time there may not be a lack of church ministers and other learned people, we are determined to establish from the confiscated monasteries and church endowments three schools, one in Meissen with one master, three bachelors, one cantor, and sixty boys; the second at Merseburg with one master, two bachelors, one cantor, and seventy boys; the third at Pforta with one master, three bachelors, one cantor and one hundred boys, freely provided and maintained in all

places with directors, servants, furniture, and all that is necessary." In 1550 the school at Merseburg was transferred to Grimma. The three schools, then, Meissen, Grimma, and Pforta, were intended for the education of boys from the state of Saxony. Board and education were free; the age of admission was from twelve to fourteen, and the prerequisite was a good grounding in elementary subjects and the beginnings of Latin. Vacancies were filled by cities, the nobility, and sovereigns. Able boys were carefully selected. Pupils were received from other states, but at high fees. The schools provided a six years' course of study in preparation for the universities, especially Leipzig and Wittenberg. A definite course of study was established by the Saxon Church Ordinance of 1580. The Fürstenschulen have had a continuous history up to the present, and have contributed a large number of men who attained eminence in political and literary life.

**FUSION.** -- This term is used in psychology to describe the process of combination and organization of elements into complex mental wholes. Thus, when one takes a substance into the mouth, he has an experience which is

a fusion of taste and odor. The fusion in this case is so intimate that analysis is practically impossible without experimental methods. Another example of fusion is the combination of present visual experience with past tactual experience, as in the case of one's recognition of a hard object which he does not touch, but merely sees. Through fusion an element of consciousness takes on a value which it could not have in itself. Thus, the color of the object seen may lead to the recognition of the hardness or roughness of the substance. Hardness and roughness are not in the color experience proper, but are added meanings. Fusion is therefore a significant phase of mental development. The more completely the mind is equipped with the elements necessary for productive fusions, and the more the individual acquires the habits of complete fusions, the more significant any new experience. The educational processes involved in developing fusions are significant in contrast with those educational activities which merely tend to give new elements, especially when little heed is paid to the process by which these elements shall gain value through combination with the others. There are all grades of intimacy in mental fusions; sometimes the elements are inseparable, at other times easily distinguishable. Fusion is used in a special sense in describing the combination of tonal sensations. Some tonal fusions depend upon processes of combinations in the organ of sense, others upon perceptual fusions. C. H. J.

books by the same author or on kindred subjects.

# A Brief Course in the History of Education

By PAUL MONROE, Ph.D.

*Cloth. Ill. 12mo. \$1.25.*

A treatment of the important topics in the history of education following the laws laid down in *A Textbook in the History of Education* by the same author. The text aims to retain the merits sought for in the larger text, namely, to suggest, chiefly by classification of this material, interpretations that will not consist merely in unsupported generalizations; to give, to some degree, a flavor of the original sources of information; to make evident the relation between educational development and the other aspects of the history of education; to deal with educational tendencies rather than with men; to show the connection between educational theory and actual school work in its historical development; to suggest relations with present educational work.

## TABLE OF CONTENTS

- Primitive Peoples : Education in its Simplest Form.
- Oriental Education : Education as Recapitulation. China as a Type.
- The Greek People : The Liberal Education.
- The Romans : Education as Training for Practical Life.
- The Middle Ages : Education as Discipline.
- The Renaissance and the Humanistic Education.
- The Reformation, Counter Reformation and the Religious Conception of Education.
- Realistic Education.
- The Disciplinary Conception of Education : John Locke.
- The Naturalistic Tendency in Education : Rousseau.
- The Psychological Tendency in Education.
- The Scientific Tendency in Education.
- The Sociological Tendency.
- Conclusion : The Present Electric Tendency.

# A Brief Course in the Teaching Process

By GEORGE DRAYTON STRAYER, Ph.D.

*Cloth. 12mo. \$1.25.*

This book is the direct outcome of experience in trying to help teachers grow in skill in the art of teaching and in power to appreciate the work in which they are engaged. The problems which the teachers face day after day in the classroom are treated as concretely as possible. Theories of education have not been discussed at any great length, but rather those processes through which these fundamental principles find their expression in actual teaching.

Each of the several typical methods of instruction has been treated, and the validity of the particular practice indicated in terms of the end to be accomplished, as well as the technique to be used. Since the art of the teaching method is not the only element in determining the efficiency of the teacher, there is included a discussion of those other aspects that determine the contribution that is made by the teacher to the education of children.

## TABLE OF CONTENTS

The Aim of Education	Questioning
The Factors Conditioning the Teaching Process	Social Phases of the Recitation
The Teaching Process	The Physical Welfare of Children
The Drill Lesson	Moral Training
The Inductive Lesson	Class Management
The Deductive Lesson	Lesson Plans
The Lesson for Appreciation	The Teacher in Relation to Supervision
The Study Lesson	The Teacher in Relation to the Course of Study
Review or Examination Lesson	Measuring Results in Education
The Recitation Lesson

# SCHOOL HYGIENE

By FLETCHER B. DRESSLAR, Ph.D.

*Cloth. Ill. 12mo. \$1.25.*

An accurate discussion of the entire subject of school hygiene, its present applications with the points of departure and the direction of progress for future development clearly indicated and constructively presented. Important topics of school hygiene have been discussed in a simple and untechnical way that appeals to teachers and general readers.

## TABLE OF CONTENTS

Introductory: The Meaning of Hygiene and Its Relation to Education
Play and Playgrounds
Location and Construction of School Buildings
Lighting of Schoolhouses
School Desks
School Baths
Convenient and Sanitary Water Supply for School Buildings
Drinking Cups and Drinking Fountains
Toilets for Schools
The Need of Pure Air
Ventilation
Open-air Schools
Heating of Schoolrooms
Humidity in the Schoolroom
Eye Defects and School Conditions
The Hearing of School Children
The Teeth of School Children
Stuttering
Fatigue
Hygiene of Instruction
The Care of Exceptional Children
Medical Inspection of School Children
Hygiene of School Utensils and Books
Cleaning Schoolrooms
Qualifications and Duties of a School Janitor
Disinfectants

# Cyclopedia of American Agriculture

Edited by LIBERTY HYDE BAILEY

*Complete in four quarto volumes. \$20.00 net.*

A comprehensive treatment of agriculture in America, in four volumes, prepared by practical experts, scientific investigators, and experienced farmers. It is an original, thoroughgoing, up-to-date, and helpful treatise.

## VOLUME I, FARMS

treats the farm and its tillage, and the agricultural characteristics of farms throughout the sections of the United States and Canada.

## VOLUME II, FARM CROPS

treats the products of agriculture and of the farmers' husbandry in relation to plants. It contains an extensive treatment of the agriculture of the farm and the garden and the many home projects associated with intensive farming.

## VOLUME III, FARM ANIMALS

is a comprehensive study of the live stock to be found on the American farm. It is of practical value to every one who owns or cares for live stock in this country.

## VOLUME IV, SOCIAL ECONOMY IN THE COUNTRY

is a study of the great series of life occupations on which the welfare of the people of this country rests. Every human relationship and aspiration that finds expression in rural life is thoughtfully considered and discussed.

The **Cyclopedia of American Agriculture** covers every phase of American agriculture. It is invaluable to every practical farmer, to every person who owns a farm, and to every person who is interested in rural life in any form.
